### Natural Language Generation

COMP-599 Nov 17, 2015

## Announcements

If you are submitting your project for peer review, do so on myCourses by Thursday, 11:59pm.

Procedure:

- I will check to make sure it has sufficiently progressed to be useful to get feedback
- Assign your paper to other students who submitted for peer review
- Peer reviews due next week

# Outline

Steps in NLG Canned Text and Template Filling Surface realization FUF/SURGE Text-to-text generation Sentence compression Sentence fusion

# Natural Language Generation

Let's compare understanding and generation Concerns of NLU:

- Ambiguity (e.g., get all possible parses)
- Disambiguation
- Underspecification

Concerns of NLG:

- Selecting appropriate content
- Selecting appropriate form to express content

### **Canned Text**

## Weather Tweets: Template Filling

Good for restricted domains.

Environment Canada's weather alert Twitter feeds: <u>https://twitter.com/ECAlertQC147</u>

What is the generation template?

# Steps in NLG

One potential architecture for an NLG system:

- 1. Content selection
- 2. Document structuring
- 3. Microplanning
- 4. Surface realization

# **Content Selection**

Deciding what to say

Ingredients:

Communicative goal

Knowledge about the world

Application-specific

How did we approach content selection last class in multidocument summarization?

# **Document Structuring**

Deciding how to structure the contents of the output What order should they be presented in? Some factors:

- Importance of the concepts
- Discourse relations
- Coherence

e.g., **Argumentation Theory** gives some guidelines on how to arrange information

- Present main claims first
- Arrange and discuss supporting evidence
- Present and debate opposing evidence

(Carenini and Moore, 2006)

# Microplanning

#### Selecting lexical items

 (BLZRD, -5, -10, 30km/h, MONTREAL) -> blizzard, low, high, wind speed, Montreal

Deciding how they fit together into clauses and sentences (sentence planning or aggregation)

- First sentence: present location and time that weather forecast pertains to
- Second sentence: present details of forecast

Generating referring expressions

• Justin Pierre James Trudeau PC MP; Justin Trudeau; the Prime Minister; Mr. Trudeau; that guy; he; him

# **Surface Realization**

Convert fully specified discourse plan to output form (individual sentences, or other kinds of output)

Different possible levels of input specification:

- Highly detailed semantic structure, with all decisions made already (lexical items, tense, aspect and mood of verbs, referring expressions, etc.)
- Shallower kinds of semantics (e.g., similar to a dependency tree)

## **Reusable Components**

There have been few standard tools or task definitions in NLG:

**Referring expression generation** 

Surface realization

Let's look at a surface realization system: FUF/Surge

# **FUF/SURGE**

A cascade of deterministic rules to convert a structured semantic representation to a string:

#### (Elhadad and Robin, 1996)

# **Components in FUF/SURGE**

- 1. Map thematic structures (i.e., semantic roles) to syntactic roles
  - e.g., agent -> subject
- 2. Handle syntactic alternations e.g., active-passive, dative alternation
- 3. Fill in default features, agreement features e.g., NPs are definite, if not otherwise specified subject and verb agree in number
- 4. Handle closed-class words

e.g., [cat pers\_pro, gender feminine] -> *she* 

# **Components in FUF/SURGE**

- 5. Order components with respect to each other e.g., subject > verb-group > indirect-object > direct object
- 6. Fill in inflections

e.g., to hand -> hands

7. Linearize the tree into the final string, using precedence constraints

# Nitrogen (Langkilde and Knight, 1998)

Use corpus statistics to help us make decisions. See HW4 <sup>©</sup>

# A Matter of Inputs

Traditional NLG: data-to-text

#### What about starting from other text?

e.g., summarization can be seen as text-to-text generation

Advantages?

Disadvantages?

# **Goals of Text-to-Text Generation**

Since we are already starting with some text, there must be something about the input that we are changing to produce the output:

Length

Informative summarization

- Complexity
   Text simplification
- Other factors?

# **Sentence Compression**

#### (Knight and Marcu, 2000)

#### Assumptions:

- May drop some words in original sentence
- Remaining words stay in the same order

#### Example:

- Orig: Beyond the basic level, the operations of the three products vary widely.
- Noisy-C: The operations of the three products vary widely.
- Human: The operations of the three products vary widely.

# **Noisy-Channel Model**

#### View as a noisy-channel model

Compression = finding  $\operatorname{argmax}_{s} P(s)P(t|s)$ 

# **Components of Model**

P(s) – language model – combine a bigram language model with a PCFG language model

P(t|s) – probably of long string given short string View as a series of PCFG rule expansions:

Assign a probability to each operation that maps from a rule in *s* to a rule in *t*.

## Example: P(s1)

P(s1) = $P(TOP \rightarrow G)$  $P(G \rightarrow H A)$  $P(H \rightarrow a)$  $P(A \rightarrow C D)$  $P(C \rightarrow b)$  $P(D \rightarrow e)$ P(a|START)P(b|a)P(e|b)P(END|e)

# Example P(t | s1)

$$P(t|s1) =$$

$$P(G \rightarrow HA|G \rightarrow HA)$$

$$P(A \rightarrow CBD|A \rightarrow CD)$$

$$P(B \rightarrow QR)$$

$$P(Q \rightarrow Z)$$

$$P(Z \rightarrow c)$$

$$P(R \rightarrow d)$$

## **More Details**

To learn the model probabilities, need a corpus of sentences with simplifications.

Need a little more work to:

- Align PCFG productions between *s* and *t*
- Efficiently search for the best possible *s* given a trained model
- See paper for details

# Sample Output

- Orig: Arborscan is reliable and worked accurately in testing, but it produces very large dxf files.
- Noisy-C: Arborscan is reliable and worked accurately in testing, but it produces very large dxf files.
- Human: Arborscan produces very large dxf files.
- Orig: Many debugging features, including user-defined break points and variable-watching and message-watching windows, have been added.
- Noisy-C: Many debugging features, including user-defined points and variable-watching and message-watching windows, have been added.
- Human: Many debugging features have been added.

## **Sentence Fusion**

(Barzilay and McKeown, 2005; Filippova and Strube, 2008; Thadani and McKeown, 2013; Cheung and Penn, 2014)

Combine information from multiple sentences. Take a *union* of information.

Bohr studied at the University of Copenhagen and got his PhD there.

After graduating, he studied physics and mathematics at the University of Copenhagen.

After graduating, Bohr studied physics and mathematics at the University of Copenhagen and got his PhD there.

## Step 1: Sentence Graph

Create a **sentence graph** by merging the input sentences' dependency trees at the nodes with the same words.

e.g.: *He <u>studied</u> sciences with pleasure.* 

+ He <u>studied</u> math and physics with Bohr.

(Filippova and Strube, 2008)

# Step 2: Extract a New Sentence

Select a subset of nodes in sentence graph that will form a new dependency tree, from which a new sentence can be generated.

**Problem**: many desiderata and constraints

- Nodes must form a tree
- Selected nodes must contain the important words
- Selected nodes should make sense in relation to each other
- Desired output length

Would like a method that allows us to write down all of these hard and soft constraints

## **Solution: Integer Linear Programming**

For each edge in the sentence graph from word *h* to word *w* with label *l*, create a variable  $x_{hw}^{l}$ .

 $x_{hw}^{l} = \begin{cases} 1 & \text{select this edge} \\ 0 & \text{don't select this edge} \end{cases}$ 

Optimize the following objective:

$$f(X) = \sum_{x} x_{hw}^{l} \times P(l|h) \times I(w)$$

"Grammaticality" – how often this head word generates a dependent with this label Importance of the dependent

## **Constraints in ILP**

maximize  $f(X) = \sum_{x} x_{hw}^{l} \times P(l|h) \times I(w)$ subject to

$$\begin{aligned} \forall w \in W, \sum_{h,l} x_{hw}^l &\leq 1 \\ \forall w \in W, \sum_{h,l} x_{hw}^l - \frac{1}{|W|} \sum_{u,l} x_{wu}^l &\geq 0 \end{aligned}$$

First constraint ensures each word has at most one head Second ensures that selected nodes form a connected tree

How would we constrain the number of words in the output?

# **ILP for NLG**

Various other syntactic and semantic constraints

e.g., ensure that conjoints are similar to each other (*math* and physics is likely, math and Bohr is unlikely)

In general, ILP is popular for NLG:

- Allows *declarative* specification of diverse objectives and constraints
- Can be solved fairly efficiently using off-the-shelf solvers http://lpsolve.sourceforge.net/5.5/ http://www-

01.ibm.com/software/commerce/optimization/cplexoptimizer/

## **Brainstorm**

How can you formulate multi-document extractive summarization as an ILP? What would be the objective and what would be some constraints?

How can you formulate sentence compression as an ILP? What would be the objective and what would be some constraints?
