

Python!

Basic types and operations

Lecture 6 - COMP 364
January 26, 2010, updated 2012
Derek Ruths

Next Lecture

- Trottier 3070 (3rd floor)
- Come a little early if you don't have an account on the Computer Science computers
- We will experiment with some Python features

What is Python?

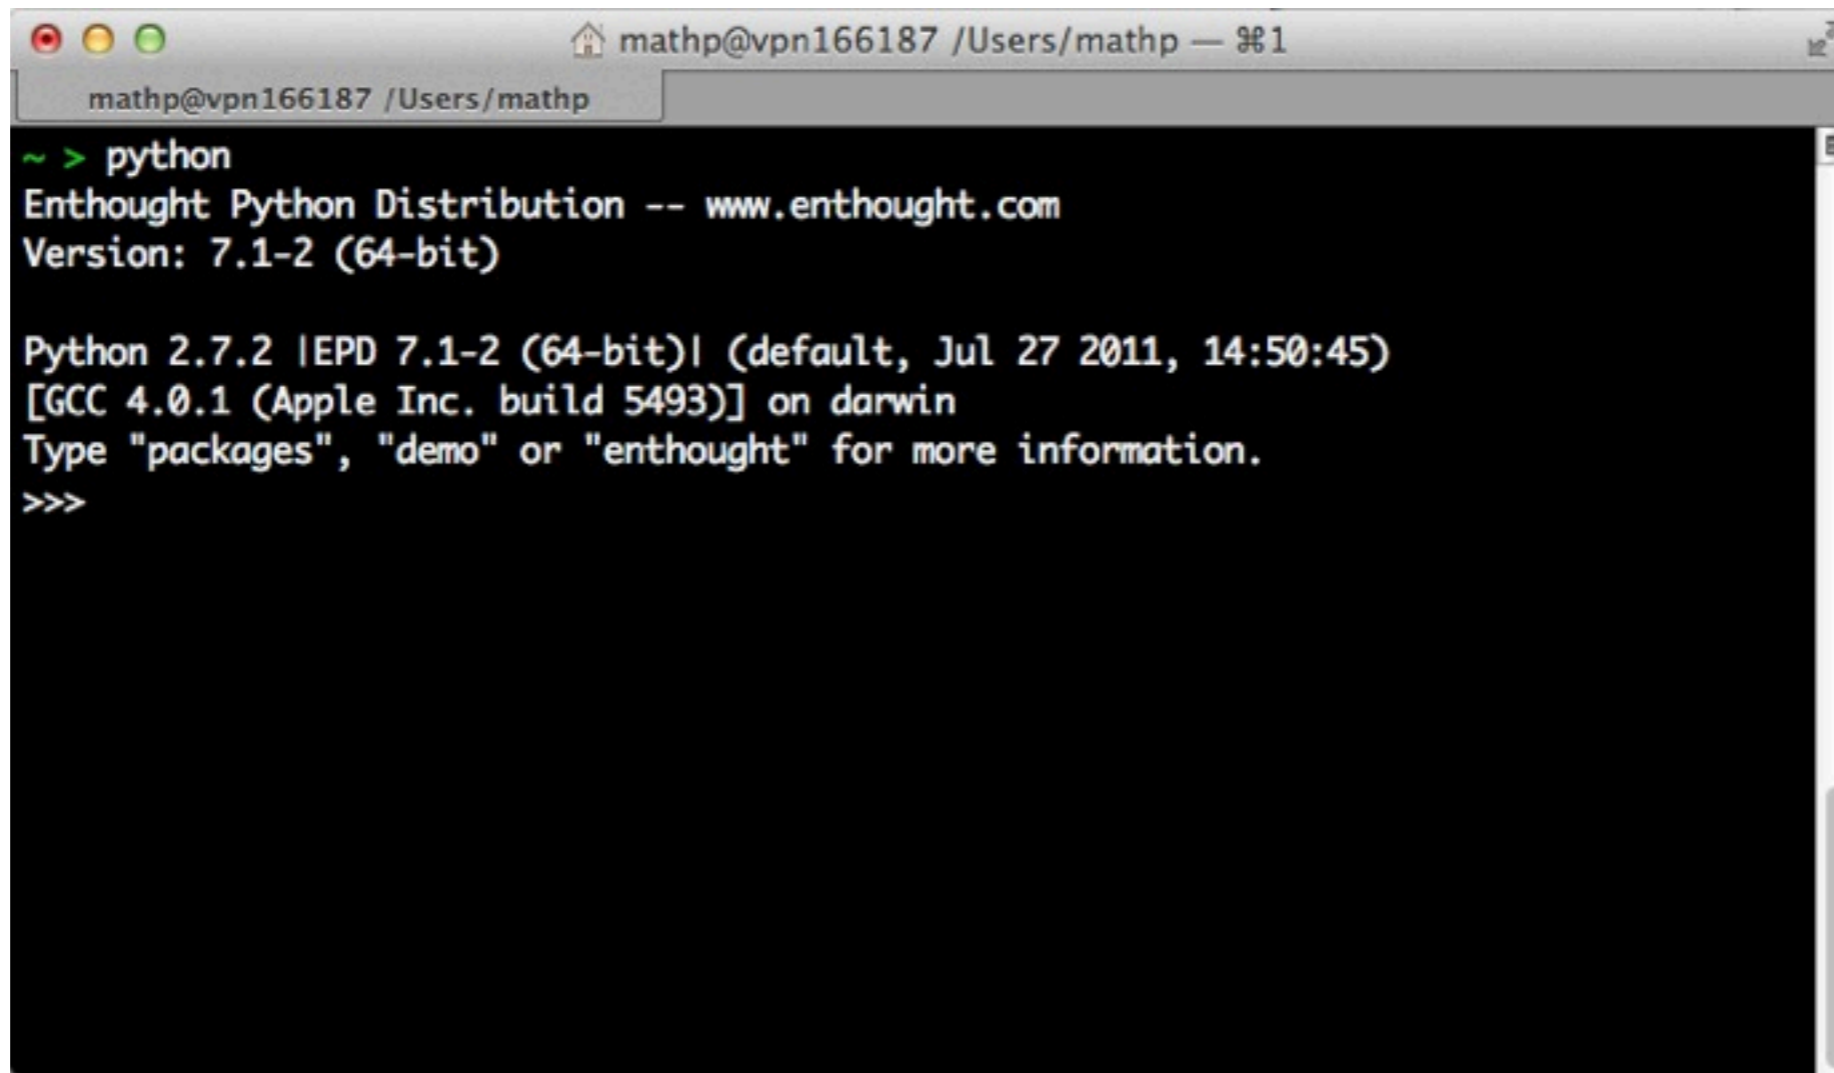

- Python: a scripting language
 - Perform more advanced operations on data
- Python: a programming language
 - Develop sophisticated applications that provide a user-friendly way of performing complex tasks on the computer
- Python: simply awesome

Installing Python on your machine

- The Enthought distribution contains all packages that we will need.
 - http://download.enthought.com/epd_7.2/
- Mac  [epd-7.2-2-macosx-i386.dmg](#)
- Linux (Ubuntu)  [epd-7.2-2-rh5-x86.sh](#)
- Windows  [epd-7.2-2-win-x86.msi](#)
- Install it on your machine now!

Starting the python console

- Run “python” on UNIX (or /usr/bin/python).
- On Windows, run the Python Command Line in the start menu

A screenshot of a terminal window on a Mac OS X system. The window title bar shows the user 'mathp' at host 'vpn166187' in the directory '/Users/mathp'. The terminal content shows the command 'python' being executed, which outputs the version information for the Python 2.7.2 distribution from Enthought, including the version number '7.1-2 (64-bit)', the Python version '2.7.2', and the compiler 'GCC 4.0.1'. The prompt '>>>' is visible at the end of the output.

```
mathp@vpn166187 /Users/mathp — 1
mathp@vpn166187 /Users/mathp
~ > python
Enthought Python Distribution -- www.enthought.com
Version: 7.1-2 (64-bit)

Python 2.7.2 |EPD 7.1-2 (64-bit)| (default, Jul 27 2011, 14:50:45)
[GCC 4.0.1 (Apple Inc. build 5493)] on darwin
Type "packages", "demo" or "enthought" for more information.
>>>
```

Our first python “program”

```
>>> print “Hello world”
```

A python command that
prints whatever comes after it

A string

Some types of objects in python

- String: always in single or double quotes
 - *“Hello world”*
 - *‘Hello world’*
- Integer: a number (no decimal)
 - 3
- Float: a number with a decimal place
 - 3.2
- Boolean: True or False
 - *True*
 - *False*

All of these are printable!

Operators

- +
 - Numbers (integer & float): add
 - String: concatenate (“Hello “ + “World” = “Hello World”)
- -
 - Numbers: subtract
- *
 - Numbers: multiply
- /
 - Numbers: divide

Arithmetic expressions

- General rules:
 - If same types are involved, stick with that type
 - If different types are involved, move to the more “accurate” type
- $\text{Int} + \text{Float} = \text{Float}$
 - $2 + 2.3 = 4.3$
- $\text{Int} / \text{Float} = \text{Float}$
 - $5 / 1.5 = 3.33333\dots$
- $\text{Int} / \text{Int} = \text{Int}$
 - $5 / 2 = 2$
 - Python will round the result to the nearest integer!

All of these are printable too!

The Syntax Error

```
>>> print "Hello world"  
>>> + 4 "Hello"
```

A syntax error: a problem with your code in which you didn't follow the rules of the language.

- Which of the following contain syntax errors?
 - The eat tree sixteen quickly. (in English)
 - "Hello" - 2.3 (in python)
 - "Hello" + 'hi (in python)
 - encho "Hello world" (in the shell)
 - The tree parked the car. (in English)

Variables

- Variables are placeholders for values they contain
 - \$1 was a variable in batch scripts
- In python, a variable can contain pretty much *anything*
- *Assignment* is when you give a variable the value it will contain
 - $x = \text{"hello"}$
 - $x = 2$
 - $x = 10.3$
- After being assigned a value, a variable can be used anywhere its value could be used:
 - $x = \text{"hello"}$
 - $\text{print } x$
 - $\text{print } x + \text{" world"}$

Assignments, and what is evaluated first

- When writing an assignment expression (e.g. `x = x + 3`), the right side is always evaluated first, then the assignment is made.

```
>>> x = "Hello "      # Assign "Hello " to x
>>> y = x
>>> x = x + "World"   # "World" is added to x ("Hello "), then new
value ("Hello World") is assigned to x
>>> print x
Hello World
>>> print y
```

- What does the last command print?

Assignments, and what is evaluated first

- When writing an assignment expression (e.g. `x = x + 3`), the right side is always evaluated first, then the assignment is made.

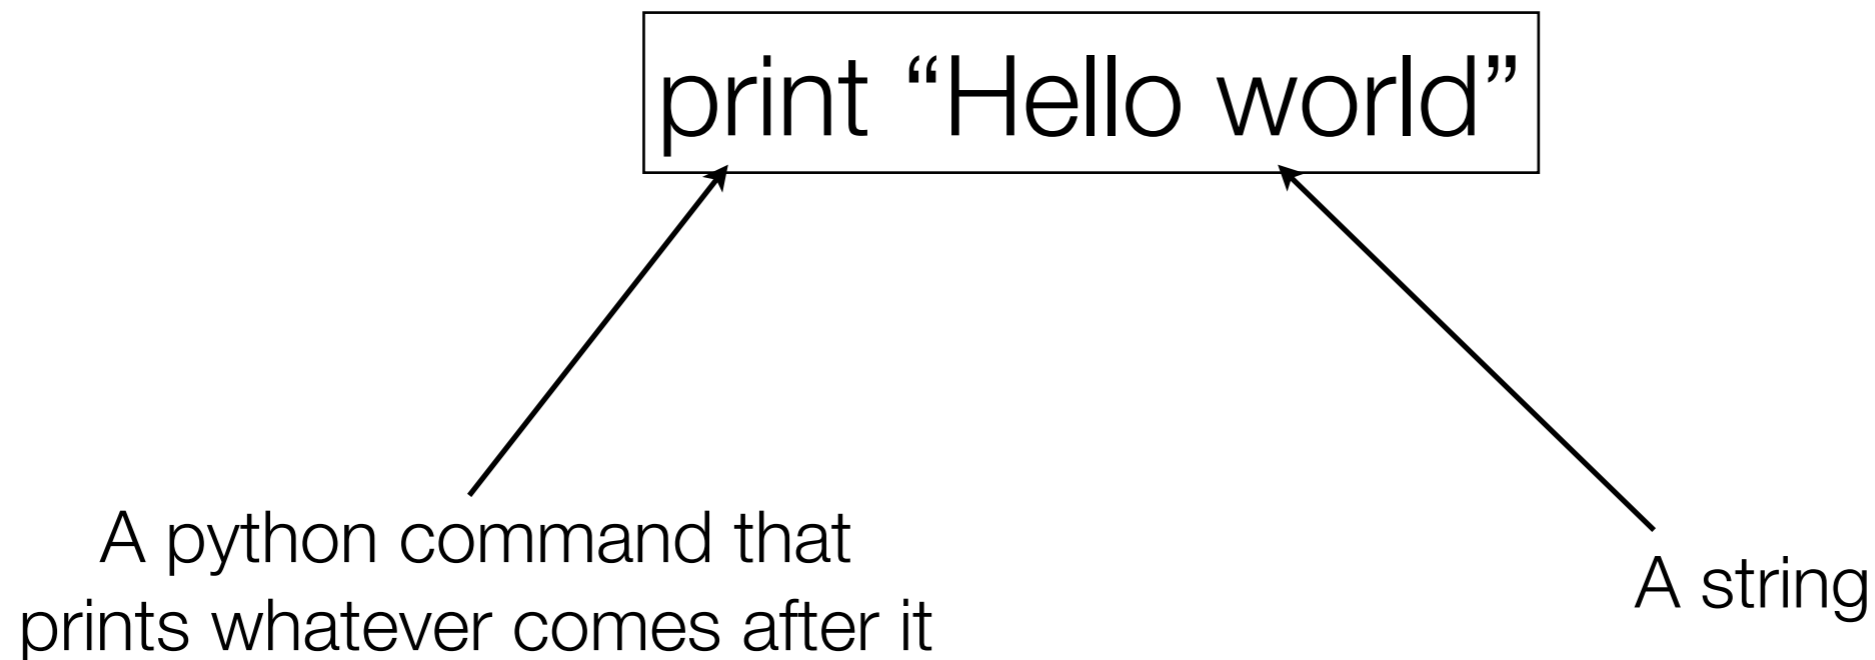

```
>>> x = "Hello "      # Assign "Hello " to x
>>> y = x
>>> x = x + "World"   # "World" is added to x ("Hello "), then new
value ("Hello World") is assigned to x
>>> print x
Hello World
>>> print y
```

- What does the last command print?

```
>>> print y
Hello
```

Our first python program

In a normal text file:

Then run it with by typing `python <filename>`

Comments

- Anything after “#” on a line will not get evaluated
 - Used for commenting, or describing what is going on
- Using this principle, putting # before a line will not execute it.
