# Overview

### MIPS assembly syntax (ChatGPT-generated)

```
<program>
             ::= <line> | <line> <program>
ine>
             ::= <label def>? <instruction> <comment>?
               | <label def>? <directive> <comment>? | <comment>
<label_def> ::= <label> ":"
<label> ::= <identifier>
<identifier> ::= [a-zA-Z_][a-zA-Z0-9_]*
<instruction> ::= <r type> | <i type> | <j type>
             ::= <opcode_r> <reg> "," <reg> "," <reg>
<r_type>
<i type>
             ::= <opcode_i> <reg> "," <reg> "," <imm>
<j_type> ::= <opcode_j> <label>
<reg> ::= "$" <num> | "$zero" | "$ra" | "$sp" | "$t0" | "$v0"
<num> ::= [0-9]+
<imm> ::= <integer>
<directive> ::= "." <directive_keyword> <directive_value>?
<directive_keyword> ::= "data" | "text" | "word" | "space" | ...
<directive_value> ::= <integer> | <label> | <string>
             ::= "#" <text>
<comment>
<text> ::= .*
<opcode r> ::= "add" | "sub" | "and" | "or" | ...
<opcode i> ::= "lw" | "sw" | "addi" | "beg" | "bne" ...
<opcode_j> ::= "j" | "jal"
                                                              3
```

#### .data

Data section: constant and variable definitions go here (including statically allocated arrays)

- format for declarations: name: storage\_type size/value
- create storage for a variable:
  - var1: .word 3 # one word storage with initial value 3
  - arr1: .space 40 # 40 bytes storage (no initial value)

#### .text

Text section: assembly instructions go here

| Category                    | Example            |
|-----------------------------|--------------------|
| Comment                     | # I am a comment   |
| Assembler directives        | .data, .asciiz     |
| Operation mnemonic          | add, addi, lw, bne |
| Register name               | \$zero, \$t3       |
| Address label (declaration) | loop1:             |
| Address label (use)         | loop1              |
| Integer constant            | 8, -4, 0xA9        |
| Character constant          | 'h', '\t'          |
| String constant             | "Hello, world\n"   |

### Hello world example

```
# A simple hello world program
```

.data

hellostr: .asciiz "Hello, world\n"

.text

| li \$v0, 4                      | # setup print syscall                           |
|---------------------------------|---|
| la <mark>\$a0</mark> , hellostr | <pre># argument to print string</pre>           |
| syscall                         | <pre># tell the OS to do the system call</pre>  |
| li <mark>\$v0,</mark> 10        | # setup exit syscall                            |
| syscall                         | <pre># tell the OS to perform the syscall</pre> |

Registers

- 32 general-purpose registers
- register preceded by \$ in MIPS assembly language
- two formats: name (\$zero) or number (\$0)
- holds 32 bits value (= 4 bytes = 1 word)
- stack grows from high memory to low memory

## Registers

| Register | Alternative | Description   |
|----------|-------------|---|
| number   | name        |   |
| 0        | \$zero      | the value 0   |
| 1        | \$at        | assembler temporary: reserved by the assembler                  |
| 2-3      | \$v0-\$v1   | function return values  |
| 4-7      | \$a0-\$a3   | function arguments: first four parameters for function (no pre- |
|          |             | served across function call)                                    |
| 8-15     | \$t0-\$t7   | temporaries (not preserved across function calls)               |
| 16-23    | \$s0-\$s7   | saved temporaries (preserved across function calls)             |
| 24-25    | \$t8-\$t9   | temporaries: (not preserved across function calls)              |
| 26-27    | \$k0-\$k1   | reserved for use by the interrupt/trap handler                  |
| 28       | \$gp        | global pointer : base of global data segment                    |
| 29       | \$sp        | stack pointer : points to last location on stack                |
| 30       | \$s8/\$fp   | saved value / frame pointer (preserved across function call)    |
| 31       | \$ra        | return address  |

• Special Hi and Lo registers (not shown above) holds result of multiplication and division (see example later)

Arithmetic

- Most use three operands
- All operands are registers or immediate values (Load/Store architecture)
- All operands are 4 bytes (a word)

| Arithmetic & Move Instruction Examples   |   |  |  |
|--|---|--|--|
| add  | <pre>\$t0,\$t1,\$t2 # \$t0 = \$t1 + \$t2;<br/># add as signed (2's complement) integers</pre>   |  |  |
| sub<br>addi<br>addu<br>subu  | <pre>\$t2,\$t3,\$t4 # \$t2 = \$t3 - \$t4 \$t2,\$t3, 5 # \$t2 = \$t3 + 5; "add immediate" \$t1,\$t6,\$t7 # \$t1 = \$t6 + \$t7; add as unsigned integers \$t1,\$t6,\$t7 # \$t1 = \$t6 + \$t7; subtract as unsigned integers</pre> |  |  |
| mul  |   |  |  |
| <pre>mult \$t3,\$t4 # multiply 32-bit quantities in \$t3 and \$t4, and store 64-bit # result in special registers Lo and Hi: (Hi,Lo) = \$t3 * \$t4</pre> |   |  |  |
| <pre>div \$t5,\$t6 # Lo = \$t5 / \$t6 (integer quotient)</pre>   |   |  |  |
| mfhi<br>mflo   | <pre>\$t0 # move value from special register Hi to \$t0: \$t0 = Hi \$t1 # move value from special register Lo to \$t1: \$t1 = Lo</pre>  |  |  |
| move   | <b>\$t2,\$t3</b> # \$t2 = \$t3  |  |  |

Memory

## Load / Store Instructions

- Memory access only allowed with explicit load and store instructions (load/store architecture)
- All other instructions use register operands
- Load
  - **lw** register\_destination, mem\_source copy a word (4 bytes) at source memory location to destination register
  - **lb** register\_destination, mem\_source copy a byte to low-order byte of destination register (sign extend higher-order bytes)
  - **li register\_destination, value** load immediate value into destination register (pseudo-instruction)

• Store

#### • sw register\_source, mem\_destination store a word (4 bytes) from source register to memory location

• **sb register\_source, mem\_destination** store a byte (low-order) from source register to memory location

#### Example

```
.data
var1: .word 23 # declare storage for var1; initial value is 23
.text
lw $t0, var1 # load content of mem location into register $t0: $t0 = 23
li $t1, 5 # $t1 = 5 ("load immediate")
sw $t1, var1 # store content of $t1 into mem: *var1 = 5
```

**A** var1 represents a pointer to a word since it is an address.

- load address:
  - la \$t0, var1

copy memory address of var1 into register \$t0

- indirect addressing:
  - lw \$t1, (\$t0)
    load word at memory address contained in \$t0 into \$t2
  - sw \$t2, (\$t0)

store word in register \$t2 into memory at address contained in \$t0

- based/indexed addressing (useful for field access in struct):
  - lw \$t2, 4(\$t0)

load word at memory address (\$t0+4) into register \$t2

• sw \$t2, -12(\$t0)

store content of register \$t2 into memory at address (\$t0-12)

| Example                                |   |
|--|---|
| .data<br>array1: .space                | 12 # declare 12 bytes of storage                  |
| .text                                  |   |
| la <mark>\$t0</mark> , array1          | <pre># load base address of array into \$t0</pre> |
| li <b>\$t1</b> , 5                     | <pre># \$t1 = 5 ("load immediate")</pre>          |
| <mark>sw \$t1, (\$t0</mark> )          | <pre># first array element set to 5</pre>         |
| li <mark>\$t1,</mark> 13               | # \$t1 = 13                                       |
| <mark>sw \$t1,</mark> 4(\$t0)          | <pre># second array element set to 13</pre>       |
| li <mark>\$t1,</mark> -7               | # \$t1 = -7                                       |
| <mark>sw \$t1,</mark> 8( <b>\$t0</b> ) | <pre># third array element set to -7</pre>        |

#### Exercise

Write a MIPS assembly program corresponding to the following C code:

```
struct point_t {
 int x;
 int y;
};
struct point_t p;
int arr[12];
void foo() {
 p.x = 2;
 p.y = 5;
 arr[3] = 6;
```

**Control Structures** 

### **Control structures**

• Branches:

| b   | target                      | # | unconditional branch to target                    |
|-----|-----------------------------|---|---|
| beq | <pre>\$t0,\$t1,target</pre> | # | branch to target if \$t0 = \$t1                   |
| blt | <pre>\$t0,\$t1,target</pre> | # | branch to target if \$t0 < \$t1                   |
| ble | <pre>\$t0,\$t1,target</pre> | # | <pre>branch to target if \$t0 &lt;= \$t1</pre>    |
| bgt | <pre>\$t0,\$t1,target</pre> | # | branch to target if \$t0 > \$t1                   |
| bge | <pre>\$t0,\$t1,target</pre> | # | <pre>branch to target if \$t0 &gt;= \$t1</pre>    |
| bne | <pre>\$t0,\$t1,target</pre> | # | <pre>branch to target if \$t0 &lt;&gt; \$t1</pre> |

#### Example

```
addi $t0, $zero, 0 # t0 = 0
addi $t1, $zero, 10 # t1 = 10
```

loop:

```
addi $t0, $t0, 1 # t0 = t0+1
blt $t0, $t1, loop # branch to loop if t0<t1 (t0<10)</pre>
```

## **Control structures**

• Jumps:

```
j target
```

# unconditional jump to program label target

jr \$t3

- # jump to address contained in \$t3 ("jump register")
- Subroutine (function) call:

jal label # "jump and link"

- copy program counter (return address) to register \$ra (return address register)
- jump to program instruction at label
- jr \$ra # "jump register"
  - $\cdot\,$  jump to return address in \$ra (stored by jal instruction)

In case of nested function calls, the return address should be saved to the stack and restored accordingly.

System Calls

System calls are used to interface with the operating systems. For instance input/output or dynamic memory allocation.

Using system calls:

- 1. load the service number in register \$v0
- 2. load argument values in \$a0, \$a1, ...
- 3. issue the syscall instruction
- 4. retrieve return value if any

```
Example: printing integer on the console
```

```
li $v0, 1
# service 1 is print integer
```

```
add $a0, $t0, $zero
# load desired value into argument register $a0
```

syscall

#### System calls table

| Service                       | \$v0   | Arguments  | Result                |
|-------------------------------|--------|--|-----------------------|
| print integer<br>print string | 1<br>4 | \$a0 = integer to print<br>\$a0 = address of null- |                       |
| print string                  | 4      | terminated string to print                         |                       |
| print character               | 11     | \$a0 = character to print                          |                       |
| read integer                  | 5      |  | \$v0 = integer read   |
| read character                | 12     |  | \$v0 = character read |
| allocate heap                 | 9      | \$a0 = number of bytes to al-                      | \$v0 = address of     |
| memory                        |        | locate   | allocated memory      |
