

Sequential decision making
Markov Decision Processes
Dynamic Programming

Recall: Agent-Environment Interface

Agent and environment interact at discrete time steps: $t = 0, 1, 2, 3, \dots$

Agent observes state at step t : $S_t \in \mathcal{S}$

produces action at step t : $A_t \in \mathcal{A}(S_t)$

gets resulting reward: $R_{t+1} \in \mathcal{R} \subset \mathbb{R}$

and resulting next state: $S_{t+1} \in \mathcal{S}^+$

Recall: Markov Decision Processes

- If a reinforcement learning task has the Markov Property, it is basically a **Markov Decision Process (MDP)**.
- If state and action sets are finite, it is a **finite MDP**.
- To define a finite MDP, you need to give:
 - **state and action sets**
 - one-step “dynamics”

$$p(s', r | s, a) = \Pr\{S_{t+1} = s', R_{t+1} = r \mid S_t = s, A_t = a\}$$

$$p(s' | s, a) \doteq \Pr\{S_{t+1} = s' \mid S_t = s, A_t = a\} = \sum_{r \in \mathcal{R}} p(s', r | s, a)$$

$$r(s, a) \doteq \mathbb{E}[R_{t+1} \mid S_t = s, A_t = a] = \sum_{r \in \mathcal{R}} r \sum_{s' \in \mathcal{S}} p(s', r | s, a)$$

The Agent Learns a Policy

Policy at step $t = \pi_t =$

a mapping from states to action probabilities

$\pi_t(a | s) =$ probability that $A_t = a$ when $S_t = s$

Special case - *deterministic policies*:

$\pi_t(s) =$ the action taken with prob=1 when $S_t = s$

- ❑ Reinforcement learning methods specify how the agent changes its policy as a result of experience.
- ❑ Roughly, the agent's goal is to get as much reward as it can over the long run.

Recall: Return

Suppose the sequence of rewards after step t is:

$$R_{t+1}, R_{t+2}, R_{t+3}, \dots$$

What do we want to maximize?

At least three cases, but in all of them,

we seek to maximize the **expected return**, $E\{G_t\}$, on each step t .

- Total reward, $G_t =$ sum of all future reward in the episode
- Discounted reward, $G_t =$ sum of all future *discounted* reward
- Average reward, $G_t =$ average reward per time step

Recall: Episodic Tasks

Episodic tasks: interaction breaks naturally into episodes, e.g., plays of a game, trips through a maze

In episodic tasks, we almost always use simple *total reward*:

$$G_t = R_{t+1} + R_{t+2} + \dots + R_T,$$

where T is a final time step at which a **terminal state** is reached, ending an episode.

Recall: Continuing Tasks

Continuing tasks: interaction does not have natural episodes, but just goes on and on...

In this class, for continuing tasks we will always use *discounted return*:

$$G_t = R_{t+1} + \gamma R_{t+2} + \gamma^2 R_{t+3} + \dots = \sum_{k=0}^{\infty} \gamma^k R_{t+k+1},$$

where γ , $0 \leq \gamma \leq 1$, is the **discount rate**.

shortsighted $0 \leftarrow \gamma \rightarrow 1$ farsighted

Typically, $\gamma = 0.9$

Another Example: Mountain Car

Get to the top of the hill
as quickly as possible.

reward = -1 for each step where **not** at top of hill

\Rightarrow return = - number of steps before reaching top of hill

Return is maximized by minimizing
number of steps to reach the top of the hill.

Another Example: Mountain Car

Get to the top of the hill
as quickly as possible.

Reward: 1 at the top of the hill, 0 otherwise

Return: if discount < 1 , k =number of time steps, so return is γ^k

Return is maximized by minimizing
number of steps to reach the top of the hill.

A Trick to Unify Notation for Returns

- In episodic tasks, we number the time steps of each episode starting from zero.
- Think of each episode as ending in an absorbing state that always produces reward of zero:

- We can cover all cases by writing $G_t = \sum_{k=0}^{\infty} \gamma^k R_{t+k+1}$,

where γ can be 1 only if a zero reward absorbing state is always reached.

Value Functions

- The **value of a state** is the expected return starting from that state; depends on the agent's policy:

State - value function for policy π :

$$v_{\pi}(s) = E_{\pi} \left\{ G_t \mid S_t = s \right\} = E_{\pi} \left\{ \sum_{k=0}^{\infty} \gamma^k R_{t+k+1} \mid S_t = s \right\}$$

- The **value of an action (in a state)** is the expected return starting after taking that action from that state; depends on the agent's policy:

Action - value function for policy π :

$$q_{\pi}(s, a) = E_{\pi} \left\{ G_t \mid S_t = s, A_t = a \right\} = E_{\pi} \left\{ \sum_{k=0}^{\infty} \gamma^k R_{t+k+1} \mid S_t = s, A_t = a \right\}$$

Gridworld

- Actions: north, south, east, west; deterministic.
- If would take agent off the grid: no move but reward = -1
- Other actions produce reward = 0 , except actions that move agent out of special states A and B as shown.

(a)

3.3	8.8	4.4	5.3	1.5
1.5	3.0	2.3	1.9	0.5
0.1	0.7	0.7	0.4	-0.4
-1.0	-0.4	-0.4	-0.6	-1.2
-1.9	-1.3	-1.2	-1.4	-2.0

(b)

State-value function
for equiprobable
random policy;
 $\gamma = 0.9$

Policy Evaluation

Policy Evaluation: for a given policy π , compute the state-value function v_π

Recall: **State-value function for policy π**

$$v_\pi(s) \doteq \mathbb{E}_\pi[G_t \mid S_t = s] = \mathbb{E}_\pi \left[\sum_{k=0}^{\infty} \gamma^k R_{t+k+1} \mid S_t = s \right]$$

Bellman Equation for a Policy π

The basic idea:

$$\begin{aligned} G_t &= R_{t+1} + \gamma R_{t+2} + \gamma^2 R_{t+3} + \gamma^3 R_{t+4} + \dots \\ &= R_{t+1} + \gamma \left(R_{t+2} + \gamma R_{t+3} + \gamma^2 R_{t+4} + \dots \right) \\ &= R_{t+1} + \gamma G_{t+1} \end{aligned}$$

So:

$$\begin{aligned} v_\pi(s) &= E_\pi \{ G_t \mid S_t = s \} \\ &= E_\pi \{ R_{t+1} + \gamma v_\pi(S_{t+1}) \mid S_t = s \} \end{aligned}$$

Or, without the expectation operator:

$$v_\pi(s) = \sum_a \pi(a|s) \sum_{s', r} p(s', r|s, a) \left[r + \gamma v_\pi(s') \right]$$

More on the Bellman Equation

$$v_{\pi}(s) = \sum_a \pi(a|s) \sum_{s', r} p(s', r|s, a) \left[r + \gamma v_{\pi}(s') \right]$$

This is a set of equations (in fact, linear), one for each state. The value function for π is its unique solution.

Backup diagrams:

Policy Evaluation

Policy Evaluation: for a given policy π , compute the state-value function v_π

Recall: **State-value function for policy π**

$$v_\pi(s) \doteq \mathbb{E}_\pi[G_t \mid S_t = s] = \mathbb{E}_\pi \left[\sum_{k=0}^{\infty} \gamma^k R_{t+k+1} \mid S_t = s \right]$$

Recall: **Bellman equation for v_π**

$$v_\pi(s) = \sum_a \pi(a|s) \sum_{s', r} p(s', r|s, a) \left[r + \gamma v_\pi(s') \right]$$

—a system of $|S|$ simultaneous equations

Iterative Methods

$$v_0 \rightarrow v_1 \rightarrow \cdots \rightarrow v_k \rightarrow v_{k+1} \rightarrow \cdots \rightarrow v_\pi$$

a “sweep” 

A sweep consists of applying a **backup operation** to each state.

A full policy-evaluation backup:

$$v_{k+1}(s) = \sum_a \pi(a|s) \sum_{s',r} p(s',r|s,a) \left[r + \gamma v_k(s') \right] \quad \forall s \in \mathcal{S}$$

Iterative Policy Evaluation – One array version

Input π , the policy to be evaluated

Initialize an array $V(s) = 0$, for all $s \in \mathcal{S}^+$

Repeat

$$\Delta \leftarrow 0$$

For each $s \in \mathcal{S}$:

$$v \leftarrow V(s)$$

$$V(s) \leftarrow \sum_a \pi(a|s) \sum_{s', r} p(s', r|s, a) [r + \gamma V(s')]$$

$$\Delta \leftarrow \max(\Delta, |v - V(s)|)$$

until $\Delta < \theta$ (a small positive number)

Output $V \approx v_\pi$

A Small Gridworld

Policy Iteration

policy evaluation

policy improvement
“greedification”

Policy Improvement

Suppose we have computed v_π for a deterministic policy π .

For a given state s ,

would it be better to do an action $a \neq \pi(s)$?

It is better to switch to action a for state s if and only if

$$q_\pi(s, a) > v_\pi(s)$$

And, we can compute $q_\pi(s, a)$ from v_π by:

$$\begin{aligned} q_\pi(s, a) &= \mathbb{E}_\pi[R_{t+1} + \gamma v_\pi(S_{t+1}) \mid S_t = s, A_t = a] \\ &= \sum_{s', r} p(s', r \mid s, a) [r + \gamma v_\pi(s')]. \end{aligned}$$

Policy Improvement Cont.

Do this for all states to get a new policy $\pi' \geq \pi$ that is **greedy** with respect to v_π :

$$\begin{aligned}\pi'(s) &= \arg \max_a q_\pi(s, a) \\ &= \arg \max_a \mathbb{E}[R_{t+1} + \gamma v_\pi(S_{t+1}) \mid S_t = s, A_t = a] \\ &= \arg \max_a \sum_{s', r} p(s', r \mid s, a) [r + \gamma v_\pi(s')],\end{aligned}$$

What if the policy is unchanged by this?

Then the policy must be optimal!

Policy Iteration – One array version (+ policy)

1. Initialization

$V(s) \in \mathbb{R}$ and $\pi(s) \in \mathcal{A}(s)$ arbitrarily for all $s \in \mathcal{S}$

2. Policy Evaluation

Repeat

$\Delta \leftarrow 0$

For each $s \in \mathcal{S}$:

$v \leftarrow V(s)$

$V(s) \leftarrow \sum_{s',r} p(s', r|s, \pi(s)) [r + \gamma V(s')]$

$\Delta \leftarrow \max(\Delta, |v - V(s)|)$

until $\Delta < \theta$ (a small positive number)

3. Policy Improvement

policy-stable \leftarrow *true*

For each $s \in \mathcal{S}$:

$a \leftarrow \pi(s)$

$\pi(s) \leftarrow \arg \max_a \sum_{s',r} p(s', r|s, a) [r + \gamma V(s')]$

If $a \neq \pi(s)$, then *policy-stable* \leftarrow *false*

If *policy-stable*, then stop and return V and π ; else go to 2

Generalized Policy Iteration

Generalized Policy Iteration (GPI):
any interaction of policy evaluation and policy improvement,
independent of their granularity.

A geometric metaphor for convergence of GPI:

Value Iteration

Recall the **full policy-evaluation backup**:

$$v_{k+1}(s) = \sum_a \pi(a|s) \sum_{s',r} p(s', r|s, a) \left[r + \gamma v_k(s') \right] \quad \forall s \in \mathcal{S}$$

Here is the **full value-iteration backup**:

$$v_{k+1}(s) = \max_a \sum_{s',r} p(s', r|s, a) \left[r + \gamma v_k(s') \right] \quad \forall s \in \mathcal{S}$$

Value Iteration – One array version

Initialize array V arbitrarily (e.g., $V(s) = 0$ for all $s \in \mathcal{S}^+$)

Repeat

$$\Delta \leftarrow 0$$

For each $s \in \mathcal{S}$:

$$v \leftarrow V(s)$$

$$V(s) \leftarrow \max_a \sum_{s',r} p(s', r | s, a) [r + \gamma V(s')]$$

$$\Delta \leftarrow \max(\Delta, |v - V(s)|)$$

until $\Delta < \theta$ (a small positive number)

Output a deterministic policy, π , such that

$$\pi(s) = \arg \max_a \sum_{s',r} p(s', r | s, a) [r + \gamma V(s')]$$

Gambler's Problem

- ❑ Gambler can repeatedly bet \$ on a coin flip
- ❑ Heads he wins his stake, tails he loses it
- ❑ Initial capital $\in \{\$1, \$2, \dots, \$99\}$
- ❑ Gambler wins if his capital becomes \$100
loses if it becomes \$0
- ❑ Coin is unfair
 - Heads (gambler wins) with probability $p = .4$

- ❑ States, Actions, Rewards? Discounting?

Gambler's Problem Solution

Gambler's Problem Solution

Asynchronous DP

- ❑ All the DP methods described so far require exhaustive sweeps of the entire state set.
- ❑ Asynchronous DP does not use sweeps. Instead it works like this:
 - Repeat until convergence criterion is met:
 - Pick a state at random and apply the appropriate backup
- ❑ Still need lots of computation, but does not get locked into hopelessly long sweeps
- ❑ Can you select states to backup intelligently? YES: an agent's experience can act as a guide.

Efficiency of DP

- ❑ To find an optimal policy is polynomial in the number of states...
- ❑ BUT, the number of states is often astronomical, e.g., often growing exponentially with the number of state variables (what Bellman called “the curse of dimensionality”).
- ❑ In practice, classical DP can be applied to problems with a few millions of states.
- ❑ Asynchronous DP can be applied to larger problems, and is appropriate for parallel computation.
- ❑ It is surprisingly easy to come up with MDPs for which DP methods are not practical.

Summary

- ❑ Policy evaluation: backups without a max
- ❑ Policy improvement: form a greedy policy, if only locally
- ❑ Policy iteration: alternate the above two processes
- ❑ Value iteration: backups with a max
- ❑ Full backups (to be contrasted later with sample backups)
- ❑ Generalized Policy Iteration (GPI)
- ❑ Asynchronous DP: a way to avoid exhaustive sweeps
- ❑ **Bootstrapping**: updating estimates based on other estimates
- ❑ Biggest limitation of DP is that it requires a *probability model* (as opposed to a generative or simulation model)
