Modelling and Simulation

Fall Term 2001

General Information

Course title	Modelling and Simulation
Course number	CS 308-522A
Prerequisites	CS 308-251 (data structures and algorithms),
-	CS 308-302 (programming languages and paradigms),
	CS 308-350 (numerical computing).
	Some experience with object-oriented design and programming.
	If you do not have the pre-requisites for the course, the course will be
	deleted from your record by the Faculty of Science.
	This is a "project" course which means you will learn to build and use
	full modelling and simulation tools in the numerous assignments.
	You are strongly advised to not take more than one other "project" course.
Course venue	Leacock 14 (check infomcgill).
	Monday and Wednesday, 14:30 – 16:00 (starting Wednesday 5 September)
	Tentative Schedule
Enrollment Cap	Enrollment is limited to 45 students.
Instructor	Prof. Hans Vangheluwe
	McConnell Engineering room 328
	tel.: +1 (514) 398 44 46
	e-mail: hv@cs.mcgill.ca
Office hours	Monday 16:00 – 18:00 (formulate questions via e-mail first !)
TA	Dr. Juan de Lara
TA Office hours	Wednesday 16:00 – 18:00
	McConnell Engineering room 202 (Modelling, Simulation and Design Lab)

Course Goals

Objectives

The course aims to teach the generic (*i.e.*, tool and application domain independent) concepts of modelling and simulation. By the end of this course, you should have a deep understanding of the concepts of modelling and simulation of dynamic systems using a variety of formalisms. You should be able to build modelling and simulation systems (during the course only two are used, others are built from scratch). This will give you ample background to understand and use existing modelling and simulation systems. The course presents general modelling and simulation principles by applying them to concrete problems. Through the assignments

(building prototype modelling and simulation tools), some experience in structured, object-oriented design and implementation will also be acquired.

Prototype modelling tools and simulators are constructed based on the theory. This is preferred to using commercial simulation tools as it leads to much better insight.

Applications (software process modelling and simulation, reactive systems design, population dynamics analysis, traffic analysis, supermarket queueing, *etc.*) are used to illustrate the different modelling formalisms and serve as case studies for the tools built in the assignments.

Rationale and Content

In the course, a bird's eye view of the state-of-the-art in modelling and simulation is presented. Hereby, the close relationship between modelling and simulation on the one hand and the analysis and design of complex (software and hardware) systems is highlighted. A formal specification of modelling and simulation formalisms and processes reveals the need for a host of computer science techniques such as graph algorithms, compilers, computer algebra, software engineering, and graphical user interfaces. By means of these techniques, modelling and simulation tools are developed.

The modelling and simulation formalisms and tools supporting their use are themselves highly useful for the analysis, design, and implementation of complex, often embedded software systems, interacting with the physical world.

The complexity of current and future systems is not only due to a large number of components (tackled by hierarchical decomposition), but is also caused by the increasing diversity of components and problem aspects. A photocopier for example combines software, analog electronic, digital electronic, electrostatic, thermodynamic, hydraulic, ... aspects and components. To easily express the structure and behaviour of such systems, multiple formalisms must be used. Such models are a basis for documentation, analysis, formal proof, simulation what-if analysis, optimization and (embedded) application code generation.

The course presents a holistic view of the modelling and simulation enterprise. Rather than focusing on particular applications, or on specific tools, it starts from a general methodology which stresses the generic, application-independent aspects of modelling formalisms and their implementation. The main aim of the course is to provide the theoretical background, methods, techniques and tools for complex problem solving, with emphasis on the software aspects.

The formalisms covered range from Causal Block Diagrams, Differential Algebraic Equations, Forrester System Dynamics, to Finite State Automata, State Charts, Petri Nets, DEVS, and the different Discrete Event World Views. More importantly, the relationships between these, how to meaningfully couple them, as well as their relative merits and disadvantages, are investigated. For each formalism, the design and implementation of a *solver* or *simulation kernel* is presented.

From the practitioner's point of view, the course describes different modelling formalisms, existing languages and to a lesser extent, tools. From the computer scientist's point of view, the course describes the techniques and standards employed in the construction of modelling environments and simulators.

Each of the topics is introduced by means of an example, followed by a theoretical presentation, followed by a more in-depth example.

Method of Instruction

Ex cathedra lectures.

Each group of new topics will be implemented in an assignment using the "executable pseudocode" scripting language Python.

Course Materials

A course pack will be made available providing a selection of book chapters and articles.

Assignments and Evaluations

Assignments and Projects:

- 6 *small assignments* (no implementation). The lowest scoring assignment is discarded. These assignments consist of either the development of a small model (*e.g.*, of traffic behaviour at an intersection) in a particular formalism without simulation or of the use of an existing modelling and simulation system such as GPSS or PythonDEVS to obtain performance metrics through simulation.
- 3 mandatory *software development* assignments. The rationale is that the Modelling and Simulation software tools to be developed in the projects are representative for "complex" software systems. During the development, most of the typical software engineering problems will be encountered. Obviously, the development of these tools will also provide insight into the (often abstract) Modelling and Simulation concepts.
- 1 project (i.e., large assignment) chosen from a list, similar to an assignment, but larger.

Structure:

- Most of the assignments as well as the project may be worked on in teams of upto 3 members, though this is not necessary. *Individual work must be indicated* !
- The results of assignments will be presented and discussed in class.
- All assignments must be submitted entirely in the form of web-pages (including design, code, and simulation results).

Grading

Grades will be distributed over assignments, project and exam:

- 30% on 5 (out of 6) highest scoring small assignments.
- 30% on 3 implementation assignments.
- 15% on the project.
- 25% on the final exam.

If a student fails to achieve a passing mark, he/she has the option of taking a supplemental exam, which will again count for 25% of the marks. Additional work may assigned to improve assignment/project grades. Assignments and projects will be judged on:

- correctness,
- structure and completeness,
- amount of work,
- originality,
- presentation.

Original Work

You are encouraged to help each other formulate the ideas behind assignment problems, but each student is required to submit his or her own *original* work. Handing in work that is not your own, original work as if it is your own is plagiarism. See section 15 of Student Rights and Responsibilities Handbook for more details. In-class presentations will check thorough understanding of assignment results. The assignment/project presentations count for 10% of the total marks.
