Applied Machine Learning

Convolutional Neural Networks

Isabeau Prémont-Schwarz

COMP 551 (Fall 2023)

Learning objectives

understand the convolution layer and the architecture of Conv-net

- its inductive bias
- its derivation from fully connected layer
- variations of convolution layer

MLP and image data

we can apply an MLP to image data

0 253 253 23 62 224 24

first vectorize the input $\ x o \operatorname{vec}(x) \in \mathbb{R}^{784}$ feed it to the MLP (with L layers) and predict the labels $\operatorname{softmax} \circ W^{\{L\}} \circ \ldots \circ \operatorname{ReLU} \circ W^{\{1\}}\operatorname{vect}(x)$

the model knows nothing about the image structure we could shuffle all pixels and learn an MLP with similar performance how to bias the model, so that it "knows" its input is image? image is like 2D version of sequence data

let's find the right model for sequence first!

Parameter-sharing

suppose we want to convert one sequence to another $\mathbb{R}^D o \mathbb{R}^D$ suppose we have a dataset of input-output pairs $\{(x^{(n)},y^{(n)})\}_n$

consider only a single layer y = g(Wx)

example: *remove background noise from audio signal*

we may assume, each output unit is the same function shifted along the sequence

when is this a good assumption?

elements of w of the same color are tied together (parameter-sharing)

Locality & sparse weight

we may further assume each output is a **local** function of input

larger receptive field with multiple layers

...

one layer: the output units "see" 3 neighbouring inputs two layers: the output units "see" 5 neighbouring inputs

Cross-correlation (1D)

Let's look at the parameter matrix W

instead of the whole matrix we can keep the one set of nonzero values

$$w = [w_1, \dots, w_K] = [W_{c,c-\lfloor rac{K}{2}
floor}, \dots, W_{c,c+\lfloor rac{K}{2}
floor}]$$

we can write matrix multiplication as **cross-correlation** of w and x

$$y_c = gig(\sum_{d=1}^D W_{c,d} x_dig) = gig(\sum_{k=1}^K w_k x_{c-\lfloorrac{K}{2}
floor+k}ig)$$

feedforward layer: slide on the input, calculate inner product and apply the nonlinearity

Convolution (1D)

Convolution (1D)

1D convolution layer **so far**...

Convolution (2D)

similar idea of parameter-sharing and locality extends to 2 dimension (i.e. image data)

this is related to the borders

image credit: Vincent Dumoulin, Francesco Visin

Convolution (2D)

there are different ways of handling the borders

zero-pad the input, and produce all non-zero outputs (full) the output is larger than the input

 $+2 \times padding -$

Y 3x3 kernel 🕧 $\boldsymbol{\mathcal{X}}$ image credit: Vincent Dumoulin, Francesco Visin

zero-pad the input, to keep the output dims similar to input (same)

●●●○○○○○○○○○○○○●●

no padding at all (valid) the output is smaller than the input we can't stack many layers sometimes we need to maintain the width

K +

Pooling

sometimes we would like to reduce the size of output e.g., from D x D to D/2 x D/2

a combination of pooling and downsampling is used

1. calculate the output $\, ilde{y}_d = gig(\sum_{k=1}^K x_{d+k-1} w_kig)$

2. aggregate the output over different regions $y_d = \operatorname{pool}\{ ilde{y}_d, \dots, ilde{y}_{d+p}\}$

two common aggregation functions are **max** and **mean**

3. often this is followed by subsampling using the same step size

the same idea extends to higher dimensions

Strided convolution

alternatively we can directly subsample the output

Strided convolution

the same idea extends to higher dimensions

Channels

so far we assumed a single input and output sequence or image

Channels

we can also add a *bias parameter (b),* one per each output channel

$$y_{m',d_1,d_2} = g\left(\sum_{m=1}^{M} \sum_{k_1} \sum_{k_2} w_{m,m',k_1,k_2} x_{m,d_1+k_1-1,d_2+k_2-1} + b_{m'}\right)$$

$$y \in \mathbb{R}^{M' \times D_1' \times D_2'}$$

$$w \in \mathbb{R}^{M \times M' \times K_1 \times K_2}$$

$$w \in \mathbb{R}^{M \times M' \times K_1 \times K_2}$$

$$M = 3$$

$$M' = 5$$

 $b\in \mathbb{R}^{M'}$

Example

demo from: https://cs231n.github.io/convolutional-networks/

Convolutional Neural Network (CNN)

CNN or convnet is a neural network with convolutional layers it could be applied to 1D sequence, 2D image or 3D volumetric data **example:** conv-net architecture (LeNet, 1998) for digits recognition

Convolutional Neural Network (CNN)

Convolutional Neural Network (CNN)

CNN or convnet is a neural network with convolutional layers (so it's a special type of MLP) it could be applied to 1D sequence, 2D image or 3D volumetric data

example: conv-net architecture (derived from AlexNet) for image classification

Application: image classification

Convnets have achieved super-human performance in image classification

ImageNet challenge: > 1M images, 1000 classes

Application: image classification

variety of increasingly deeper architectures have been proposed

Application: image classification

variety of increasingly deeper architectures have been proposed

Visual Examples

see the interactive demo here

Training: backpropagation through convolution

consider the 1D convolution op. $y_d = \sum_k w_k x_{d+k-1}$

using backprop. we have $\frac{\partial J}{\partial u_d}$ so far and we need

1) $\frac{\partial J}{\partial w_k} = \sum_{d'} \frac{\partial J}{\partial y_{d'}} \frac{\partial y_{d'}}{\partial w_k}$ using this we can update the convolution kernel at the current layer

2) to backpropagate to previous layer

$$rac{\partial J}{\partial x_d} = \sum_{d'} rac{\partial J}{\partial y_{d'}} rac{\partial y_{d'}}{\partial x_d}$$

even when we have stride, and padding, this operation is similar to multiplication by transpose of the parameter-sharing matrix (transposed convolution)

Transposed convolution

Transposed convolution produces a larger output from a smaller input

Transposed convolution can recover the shape of the original input

no padding of the original convolution corresponds to *full* padding of in transposed version

Transposed convolution

Transposed convolution recovers the shape of the original input

no padding of the original convolution corresponds to *full* padding of in transposed version

full padding of the original convolution corresponds to no padding of in transposed version

this can be used for up-sampling (opposite of stride/pooling)

as expected the transpose of a transposed convolution is the original convolution

Solving other discriminative vision tasks with CNNs

Structured Prediction: the output itself may have (image) structure (e.g., predicting text, audio, image)

example

in (semantic) segmentation, we classify each pixel loss is the sum of cross-entropy loss across the whole image

variety of architectures... one that performs well is **U-Net**

transposed convolution (upconv), concatenation, and skip connection are common in architecture design architecture search (i.e., combinatorial hyper-parameter search) is an expensive process and an active research area

Generating images by inverting CNNs

generating images which maximize the class label

$$p(x|y) \propto p(x)p(y|x)$$
 $x_{t+1} = x_t + \epsilon_1 rac{\partial \log p(x_t)}{\partial x_t} + \epsilon_2 rac{\partial \log p(y=c|x_t)}{\partial x_t} + \mathcal{N}(0, \epsilon_3^2 I)$

e.g. using Gaussian prior we have:

$$x_{t+1} = (1-\epsilon_1)x_t + rac{\partial \log p(y=c|x_t)}{\partial x_t}$$
gradients

Images that maximize the probability of ImageNet classes "goose" and "ostrich'

e.g. using *Total variation (TV)* prior gives more realistic

Anemone Fish

Banana

Parachute

Screw

Generating images by inverting CNNs

- Deep Dream
 - generate versions of an input image that emphasize certain features by picking a layer and ask the network to enhance whatever it detected

iteratio

read more here

- Neural style transfer
 - specify a reference "style image" xs and "content image" xc.

Summary

convolution layer introduces an inductive bias (equivariance) to MLP

- translation of the same model is applied to produce different outputs (pixels)
- the layer is equivariant to translation
- achieved through parameter-sharing

conv-nets use combinations of

- convolution layers
- ReLU (or similar) activations
- pooling and/or stride for down-sampling
- skip-connection and/or batch-norm to help with optimization / regularization
- potentially fully connected layers in the end

training

- backpropagation (similar to MLP)
- SGD or its improved variations with adaptive learning rate
- monitor the validation error for early stopping
