

Distributed Information Systems: Architecture

Logical Components of Information System

□ Logical Components provide vertically layered architecture

- ☆ Client needs a presentation layer through which it can submit operations and obtain a result
- ☆ The application logic establishes what operations can be performed over the system and how they take place.
 - enforces the business rules
 - establishes the business processes
- ☆ The resource management deals with the organization (storage, indexing, and retrieval) of the data necessary to support the application logic.
 - Provides persistence and querying capability

Presentation and Application

□ Presentation Logic

☆ Web-Browser

- Static web-pages
- Dynamic web-pages

☆ Touch screen

☆ Specialized Software for banks/travel agencies/CAD

□ Application Logic

☆ BookFlight / ReserveCar / PayBill

☆ Java Classes / Java Beans

COMP-614: Distributed Data Management

Resource Manager / Services

□ Resource Management

- ☆ Persistent Object Store
- ☆ Relational Database Management System
- ☆ XML data
- ☆ File System
- ☆ Set/get data

□ System Services

- ☆ Security: Authentication / Access Control / Encryption
- ☆ Transactions: All-or-Nothing / Isolation / Durability
- ☆ Query optimization and execution
- ☆ Service/Object Location
- ☆ Communication: RMI/multicast/persistent queues
- ☆ ...

COMP-614: Distributed Data Management

Mainframe

1-tier architecture

- ❑ Clients access the system through display terminals
 - ☆ What is displayed and how it appears is controlled by server ("dumb" terminals)
 - ☆ Often limited GUI
- ❑ Typical architecture of main-frame applications.
- ❑ Advantages:
 - ☆ Highly optimized
 - ☆ Easy to keep data consistent
- ❑ Disadvantages
 - ☆ Often no conceptual separation of components
 - Little modularity
 - Experts must know all
 - ☆ Highly-available mainframe server extremely expensive
- ❑ Examples
 - ☆ Bank application (terminals with green text-only screens)

COMP-614: Distributed Data Management

Separation of presentation logic from other layers

- ❑ Move (part of) presentation layer to client
- ❑ Modern Bank Software:
 - ☆ Presentation Logic at PC/client (implemented in Swing, Applets, etc.)
 - ☆ API (application programming interface) allows the presentation logic module to call application logic methods
 - `retrieveClientaccountinfobyname(&clientname)`
 - `retrieveClientaccountinfobyid(&clientid)`
- ❑ Web-Pages
 - ☆ Powerful Web Browser at client
 - ☆ Web-page creation or webpage storage at server
 - ☆ Presentation Logic split between client and server

COMP-614: Distributed Data Management

Separation of presentation logic from other layers

Advantages:

- ☆ Individual presentation layers for different clients (web-browser, PDA browser, telephone,...)
- ☆ Use computing power at client for sophisticated presentation layer
- ☆ Introduces concept of API (application program interface)
 - Specify an interface (set of objects/methods or functions) that can be called from the outside
- ☆ Provides conceptual separation of presentation and business logic

Compare with integrated solutions

- ☆ Cgi scripts and servlets creating html AND containing SQL to call dbs

COMP-614: Distributed Data Management

Separation of application logic from storage management

Standard

- ☆ Application Logic is implemented in application programs. Access DB through JDBC, ODBC, etc.
- ☆ Application Logic client of DBS

Performance optimization

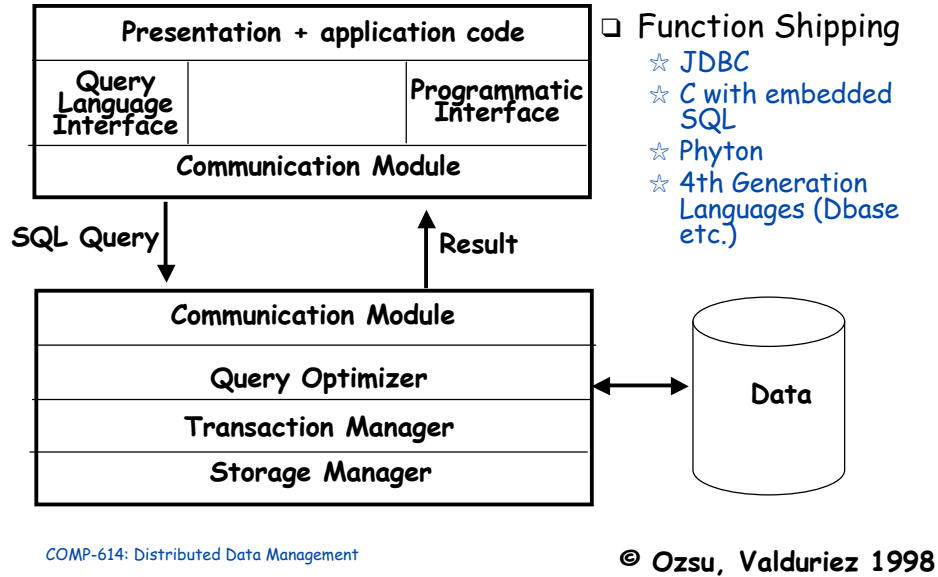

- ☆ Stored procedures: move application logic to DBS

Data Integrity

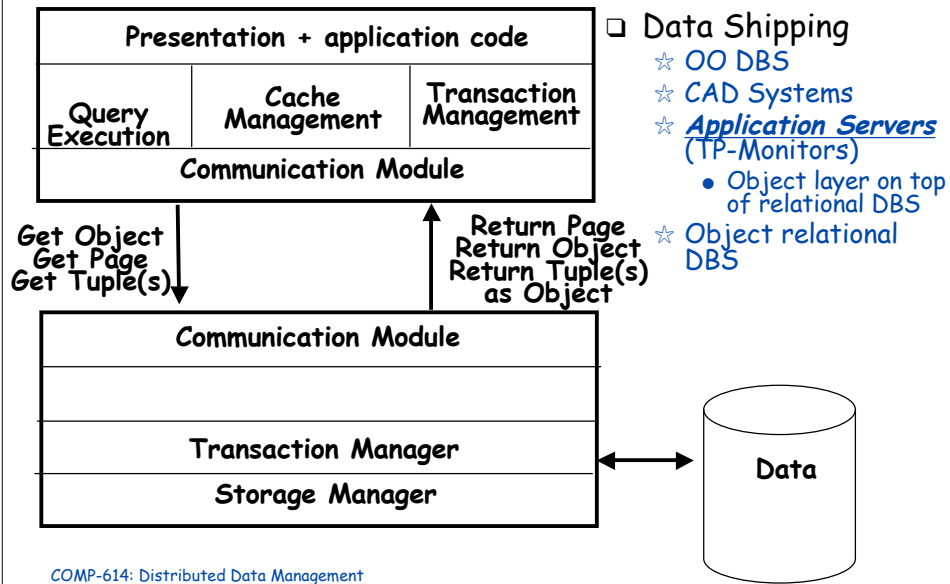

- ☆ Use triggers

COMP-614: Distributed Data Management

Location of System Services - Traditional Relational

Migration of System Services -- OO

Horizontal Distribution at different Layers

Supporting multiple client types /
Client interfaces

Separating application logic

Data Distribution and replication

COMP-614: Distributed Data Management

System Design

• There is no problem in system design that cannot be solved by adding a level of indirection.
• There is no performance problem that cannot be solved by removing a level of indirection.

- Each box is a part of the system
- The more boxes,
 - ☆ the more modular the system
 - ☆ better distribution and parallelism
 - ☆ Better encapsulation, component based design, reuse
 - ☆ Fault-tolerance?
- The more boxes, the more arrows
 - ☆ More session and connection maintenance
 - ☆ More coordination
 - ☆ More complex to monitor and manage
- The more boxes,
 - ☆ the more context switches
 - ☆ More intermediate steps for each task
 - ☆ Performance problems
- Need to balance the advantages and disadvantages of the different architectures

COMP-614: Distributed Data Management

Accessing more than one resource

Problems:

- ☆ The resource managers don't know about each other and a potential common business logic
 - Each client has to implement this
- ☆ The resource managers are probably different
 - Each client has to deal with heterogeneous environment
- ☆ Very inefficient and complex

COMP-614: Distributed Data Management

1-layer coordination

- **Parallel database systems / cluster database systems / distributed databases: e.g., all DBS are part of a single system.**
 - ☆ Client connects to any DBS node
 - ☆ Transparent forward of remote requests
 - ☆ Transparent load balancing, distributed query execution
 - ☆ Oracle
 - transparent replication
 - Supports distribution
 - Provides communication network between different database servers
 - Provides parallel database system

COMP-614: Distributed Data Management

Data Warehouse

- ❑ Data Warehouse collects and **copies** data from data sources; further processing of data for advanced analysis
- ❑ Execution and data flow:
 - ☆ Updates and standard queries: to local DBS
 - ☆ Complex queries: to data warehouse
 - ☆ Data warehouse does not forward queries but accesses own copy
 - ☆ Changes in data sources via push/pull integrated into data warehouse

COMP-614: Distributed Data Management

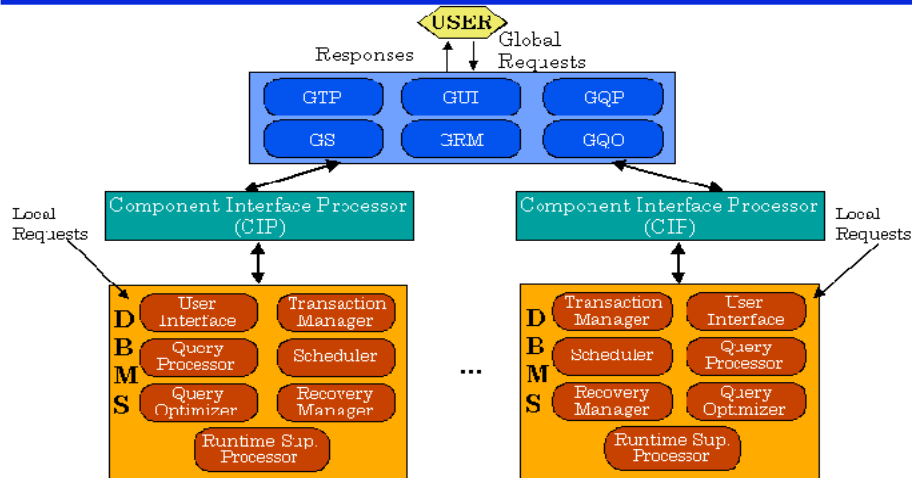

Middleware approach

- ❑ Middleware is just a level of indirection separating client from several servers
- ❑ Advantages
 - ☆ Simplify design of clients by reducing interfaces (only sees middleware)
 - ☆ Transparent access to underlying systems
 - ☆ Centralizes control
 - ☆ Functionality available to all clients
 - ☆ Is able to handle heterogeneity
 - ☆ Advanced System Services
 - Takes care of locating resources, accessing them, gathering results
- ❑ Disadvantages
 - ☆ Another indirection
 - ☆ Single Point of Failure

COMP-614: Distributed Data Management

DBS Middleware

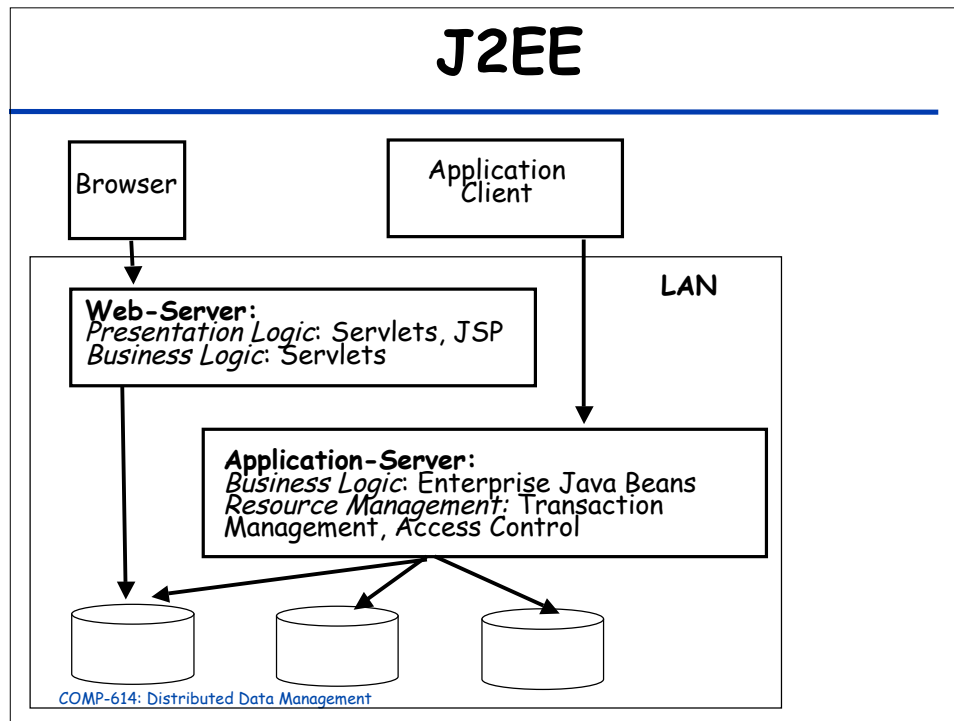

□ Tasks

- ☆ Divides user query into sub-queries to underlying (heterogeneous) data sources
- ☆ Collects results and performs post-processing (additional query processing: necessary for join over tables from different sources)
- ☆ Distributed transaction management for isolation and atomicity
- ☆ Contains meta information in order to perform tasks automatically

□ Existing systems

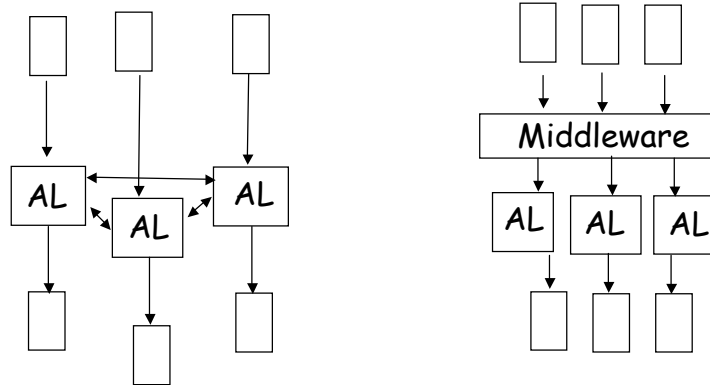

- ☆ Many research prototypes
- ☆ Commercial systems for heterogeneous query processing OR for distributed transaction processing
- ☆ J2EE Application Server
 - Restricted support for transaction isolation in case of caching (relies on underlying DBS)
 - Programmer must explicitly state for each DB call which DBS to access
 - No post-processing of queries from different data sources (programmer must do this)

COMP-614: Distributed Data Management

- ## Application Server Examples (not only J2EE)
- ❑ BEA Tuxedo (TP-Monitor)
 - ❑ BEA Weblogic (J2EE)
 - ❑ Bluestone Sapphire/Web
 - ❑ ColdFusion
 - ❑ Compaq (Tandem) Pathway
 - ❑ Compaq (DEC) ACMS
 - ❑ IBM CICS (TP-Monitor)
 - ❑ IBM IMS/DC (TP-Monitor)
 - ❑ IBM Websphere (J2EE)
 - ❑ Iona iPortal App Server
 - ❑ iPlanet (Sun/Netscape) (J2EE)
 - ❑ Microsoft COM+ (formerly MS Transaction Server, or MTS)
 - ❑ Oracle Application Server
 - ❑ SilverStream
 - ❑ WebObjects
 - ❑ And many others. See serverwatch.internet.com
- COMP-614: Distributed Data Management

Distributed Application Logic

- Distribution of system services similar to DBS case
