Conclusion

# Precomposition

- 1 Now, precomposition with  $\alpha$  in  $\mathbf{Rad}_\infty$  gives a map  $P_1(\alpha)$  from  $L_1^+(Y, q)$  to  $L_1^+(X, p)$ .
- 2 Dually, given  $\alpha \in \mathbf{Rad}_1 : (X, p) \rightarrow (Y, q)$  and  $g \in L_\infty^+(Y, q)$  we have that  $P_\infty(\alpha)(g) \in L_\infty^+(X, p)$ .
- 3 Thus the subscripts on the two precomposition functors describe the *target* categories.
- 4 Using the  $*$ -functor we get a map  $(P_1(\alpha))^*$  from  $L_1^{+,*}(X, p)$  to  $L_1^{+,*}(Y, q)$  in the first case and
- 5 dually we get  $(P_\infty(\alpha))^*$  from  $L_\infty^{+,*}(X, p)$  to  $L_\infty^{+,*}(Y, q)$ .

# Expectation value functor

- The **functor**  $\mathbb{E}_\infty(\cdot)$  is a functor from  $\mathbf{Rad}_\infty$  to  $\omega\mathbf{CC}$  which, on objects, maps  $(X, p)$  to  $L_\infty^+(X, p)$  and on maps is given as follows:

Conclusion

# Expectation value functor

- The **functor**  $\mathbb{E}_\infty(\cdot)$  is a functor from  $\mathbf{Rad}_\infty$  to  $\omega\mathbf{CC}$  which, on objects, maps  $(X, p)$  to  $L_\infty^+(X, p)$  and on maps is given as follows:
- Given  $\alpha : (X, p) \rightarrow (Y, q)$  in  $\mathbf{Rad}_\infty$  the action of the functor is to produce the map  $\mathbb{E}_\infty(\alpha) : L_\infty^+(X, p) \rightarrow L_\infty^+(Y, q)$  obtained by composing  $(P_1(\alpha))^*$  with the isomorphisms between  $L_1^{+,*}$  and  $L_\infty^+$

$$\begin{array}{ccc} L_1^{+,*}(X, p) & \leftarrow \cdots & L_\infty^+(X, p) \\ (P_1(\alpha))^* \downarrow & & \downarrow \mathbb{E}_\infty(\alpha) \\ L_1^{+,*}(Y, q) & \cdots \rightarrow & L_\infty^+(Y, q) \end{array}$$

# The other expectation value functor

The **functor**  $\mathbb{E}_1(\cdot)$  is a functor from  $\mathbf{Rad}_1$  to  $\omega\mathbf{CC}$  which maps the object  $(X, p)$  to  $L_1^+(X, p)$  and on maps is given as follows:

Given  $\alpha : (X, p) \rightarrow (Y, q)$  in  $\mathbf{Rad}_1$  the action of the functor is to produce the map  $\mathbb{E}_1(\alpha) : L_1^+(X, p) \rightarrow L_1^+(Y, q)$  obtained by composing  $(P_\infty(\alpha))^*$  with the isomorphisms between  $L_\infty^{+,*}$  and  $L_1^+$  as shown in the diagram below

$$\begin{array}{ccc} L_\infty^{+,*}(X, p) & \xleftarrow{\dots\dots\dots} & L_1^+(X, p) \\ \downarrow (P_\infty(\alpha))^* & & \downarrow \mathbb{E}_1(\alpha) \\ L_\infty^{+,*}(Y, q) & \xrightarrow{\dots\dots\dots} & L_1^+(Y, q) \end{array}$$

# The approximation map

The expectation value functors project a probability space onto another one with a possibly coarser  $\sigma$ -algebra. Given an AMP on  $(X, p)$  and a map  $\alpha : (X, p) \rightarrow (Y, q)$  in  $\mathbf{Rad}_\infty$ , we have the following approximation scheme:

## Approximation scheme

$$\begin{array}{ccc} L_\infty^+(X, p) & \xrightarrow{\tau_a} & L_\infty^+(X, p) \\ P_\infty(\alpha) \uparrow & & \mathbb{E}_\infty(\alpha) \downarrow \\ L_\infty^+(Y, q) & \xrightarrow{\alpha(\tau_a)} & L_\infty^+(Y, q) \end{array}$$

Conclusion

# The category AMP

- In  $\mathbf{Rad}_1$  and  $\mathbf{Rad}_\infty$  the morphisms obeyed mild conditions on the measures.
- These are sufficient to develop the functorial theory of expectation values.
- A map  $\alpha : (X, p) \rightarrow (Y, q)$  in  $\mathbf{Rad}_\infty$  is said to be *measure-preserving* if  $M_\alpha(p) = q$  (image measure).

## The category AMP

Objects: probability spaces  $(X, \Sigma, p)$ , along with an abstract Markov process  $\tau_a$  on  $X$ .

Arrows:  $\alpha : (X, \Sigma, p, \tau_a) \rightarrow (Y, \Lambda, q, \rho_a)$  are surjective measure-preserving maps from  $X$  to  $Y$  such that  $\alpha(\tau_a) = \rho_a$ .

# The category **AMP**

- In **Rad**<sub>1</sub> and **Rad**<sub>∞</sub> the morphisms obeyed mild conditions on the measures.
- These are sufficient to develop the functorial theory of expectation values.
- A map  $\alpha : (X, p) \rightarrow (Y, q)$  in **Rad**<sub>∞</sub> is said to be *measure-preserving* if  $M_\alpha(p) = q$  (image measure).

## The category **AMP**

Objects: probability spaces  $(X, \Sigma, p)$ , along with an abstract Markov process  $\tau_a$  on  $X$ .

Arrows:  $\alpha : (X, \Sigma, p, \tau_a) \rightarrow (Y, \Lambda, q, \rho_a)$  are surjective measure-preserving maps from  $X$  to  $Y$  such that  $\alpha(\tau_a) = \rho_a$ .

- We define the category **Rad**<sub>=</sub> to have the same objects as **AMP** but the maps are only measure preserving (and, of course, measurable).

## Larsen-Skou definition

Given an **LMP**  $(S, \Sigma, \tau_a)$  an equivalence relation  $R$  on  $S$  is called a *probabilistic bisimulation* if  $sRt$  then for every *measurable*  $R$ -closed set  $C$  we have for every  $a$

$$\tau_a(s, C) = \tau_a(t, C).$$

This variation to the continuous case is due to Josée Desharnais and her Indian friends.

- On analytic spaces the two concepts co-incide.
- Recent results show that the theory cannot be made to work with spans on general measurable spaces.

# The official definition of bisimulation

## Bisimulation

We say that two objects of **AMP**,  $(X, \Sigma, p, \tau)$  and  $(Y, \Lambda, q, \rho)$ , are *bisimilar* if there is a third object  $(Z, \Gamma, r, \pi)$  with a pair of zigzags

$$\alpha : (X, \Sigma, p, \tau) \rightarrow (Z, \Gamma, r, \pi)$$

$$\beta : (Y, \Lambda, q, \rho) \rightarrow (Z, \Gamma, r, \pi)$$

giving a cospan diagram

$$\begin{array}{ccc} (X, \Sigma, p, \tau) & & (Y, \Lambda, q, \rho) \\ & \searrow \alpha & \swarrow \beta \\ & (Z, \Gamma, r, \pi) & \end{array} \quad (3)$$

Note: identity is a zigzag.

Logical char-  
acterization

Approximation  
by finite  
spaces

Conclusion

# Pushouts explicitly

More explicitly, let  $\alpha : (X, \Sigma, p, \tau_a) \rightarrow (Y, \Lambda, q, \rho_a)$  and  $\beta : (X, \Sigma, p, \tau_a) \rightarrow (Z, \Gamma, r, \kappa_a)$  be a span in **AMP**. Then there is an object  $(W, \Omega, \mu, \pi_a)$  of **AMP** and **AMP** maps  $\delta : Y \rightarrow W$  and  $\gamma : Z \rightarrow W$  such that the diagram

$$\begin{array}{ccc} & (X, \Sigma, p, \tau_a) & \\ \alpha \swarrow & & \searrow \beta \\ (Y, \Lambda, q, \rho_a) & & (Z, \Gamma, r, \kappa_a) \\ \delta \searrow & & \swarrow \gamma \\ & (W, \Omega, \mu, \pi_a) & \end{array} \quad (4)$$

commutes.

# Couniversality

If  $(U, \Xi, \nu, \lambda_a)$  is another **AMP** object and  $\phi : Y \rightarrow U$  and  $\psi : Z \rightarrow U$  are **AMP** maps such that  $\alpha, \beta, \phi$  and  $\psi$  form a commuting square, then there is a unique **AMP** map  $\theta : W \rightarrow U$  such that the diagram

$$\begin{array}{ccc} & (X, \Sigma, p, \tau_a) & \\ \alpha \swarrow & & \searrow \beta \\ (Y, \Lambda, q, \rho_a) & & (Z, \Gamma, r, \kappa_a) \\ \delta \searrow & & \swarrow \gamma \\ & (W, \Omega, \mu, \pi_a) & \\ \phi \searrow & \downarrow \theta & \swarrow \psi \\ & (U, \Xi, \nu, \lambda_a) & \end{array} \quad (5)$$

commutes.

# Bisimulation is an equivalence

(6)

The pushouts of the zigzags  $\beta$  and  $\delta$  yield two more zigzags  $\zeta$  and  $\eta$  (and the pushout object  $V$ ). As the composition of two zigzags is a zigzag,  $X$  and  $Z$  are bisimilar. Thus bisimulation is transitive.

# Existence theorem

Given any AMP  $(X, \Sigma, p, \tau_a)$  there exists another AMP  $(\tilde{X}, \Gamma, r, \pi_a)$  and a zigzag  $\eta$  in **AMP**,  $\eta : X \rightarrow \tilde{X}$  such that  $(\tilde{X}, \Gamma, r, \pi_a)$  and  $\eta$  define a bisimulation-minimal realization of  $(X, \Sigma, p, \tau_a)$ .

Proof idea: Intersect all event bisimulations to get a smallest (fewest sets in the  $\sigma$ -algebra) event bisimulation. Define the associated equivalence relation and form the quotient.

Two AMPs are bisimilar if and only if their minimal realizations are isomorphic.

# A modal logic

We define a logic  $\mathcal{L}$  as follows, with  $a \in \mathcal{A}$ :

$$\mathcal{L} ::= \mathbf{T} | \phi \wedge \psi | \langle a \rangle_q \psi$$

Given a labelled AMP  $(X, \Sigma, p, \tau_a)$ , we associate to each formula  $\phi$  a measurable set  $\llbracket \phi \rrbracket$ , defined recursively as follows:

$$\begin{aligned}\llbracket \mathbf{T} \rrbracket &= X \\ \llbracket \phi \wedge \psi \rrbracket &= \llbracket \phi \rrbracket \cap \llbracket \psi \rrbracket \\ \llbracket \langle a \rangle_q \psi \rrbracket &= \{s : \tau_a(\mathbf{1}_{\llbracket \psi \rrbracket}) (s) > q\}\end{aligned}$$

We let  $\llbracket \mathcal{L} \rrbracket$  denotes the measurable sets obtained by all formulas of  $\mathcal{L}$ .

Conclusion

## Main theorem

Given a LAMP  $(X, \Sigma, p, \tau_a)$ , the  $\sigma$ -field  $\sigma(\llbracket \mathcal{L} \rrbracket)$  generated by the logic  $\mathcal{L}$  is the smallest event-bisimulation on  $X$ . That is, the map  $i : (X, \Sigma, p, \tau_a) \rightarrow (X, \sigma(\llbracket \mathcal{L} \rrbracket), p, \tau_a)$  is a zigzag; furthermore, given any zigzag  $\alpha : (X, \Sigma, p, \tau_a) \rightarrow (Y, \Lambda, q, \rho_a)$ , we have that  $\sigma(\llbracket \mathcal{L} \rrbracket) \subseteq \alpha^{-1}(\Lambda)$ .

Hence, the  $\sigma$ -field obtained on  $X$  by the smallest event bisimulation is precisely the  $\sigma$ -field we obtain from the logic.

# Finite approximations

Let  $(X, \Sigma, p, \tau_a)$  be a LAMP. Let

$\mathcal{P} = 0 < q_1 < q_2 < \dots < q_n < 1$  be a finite partition of the unit interval with each  $q_i$  a rational number. We call these *rational partitions*. We define a family of finite  $\pi$ -systems, subsets of  $\Sigma$ , as follows:

$$\begin{aligned}\Phi_{\mathcal{P},0} &= \{X, \emptyset\} \\ \Phi_{\mathcal{P},n} &= \pi \left( \left\{ \tau_a(\mathbf{1}_A)^{-1}(q_i, 1] : q_i \in \mathcal{P}, A \in \Phi_{\mathcal{P},n-1}, a \in \mathcal{A} \right\} \cup \Phi_{\mathcal{P},n-1} \right) \\ &= \pi \left( \left\{ \left[ \langle a \rangle_{q_i} \mathbf{1}_A \right] : q_i \in \mathcal{P}, A \in \Phi_{\mathcal{P},n-1}, a \in \mathcal{A} \right\} \cup \Phi_{\mathcal{P},n-1} \right)\end{aligned}$$

where  $\pi(\Omega)$  means the  $\pi$ -system generated by the family of sets  $\Omega$ .

# Approximation pairs

For each pair  $(\mathcal{P}, M)$  consisting of a rational partition and a natural number, we define a  $\sigma$ -algebra  $\Lambda_{\mathcal{P}, M}$  on  $X$  as  $\Lambda_{\mathcal{P}, M} = \sigma(\Phi_{\mathcal{P}, M})$ , the  $\sigma$ -algebra generated by  $\Phi_{\mathcal{P}, M}$ . We call each pair  $(\mathcal{P}, M)$  consisting of a rational partition and a natural number an *approximation pair*.

Conclusion

The following result links the finite approximation with the formulas of the logic used in the characterization of bisimulation.

## Crucial fact

Given any labelled AMP  $(X, \Sigma, p, \tau_a)$ , the  $\sigma$ -algebra  $\sigma(\bigcup \Phi_{\mathcal{P}, M})$ , where the union is taken over all approximation pairs, is precisely the  $\sigma$ -algebra  $\sigma[[\mathcal{L}]]$  obtained from the logic.

Conclusion

# Existence of a projective limit

## Main theorem

The probability spaces of finite approximants  $\hat{X}_{P,M}$  of a measure space  $(X, \Sigma, p, \tau_a)$  each equipped with the discrete  $\sigma$ -algebra (i.e. the  $\sigma$ -algebra of all subsets) indexed by the approximation pairs, form a projective system in the category **Rad**<sub>=</sub>. This system of finite approximants to the LAMP  $(X, \Sigma, p, \tau_a)$  has a projective limit in the category **Rad**<sub>=</sub>.

This uses a theorem of Choksi from 1958. In typical analysis style, he constructs the required limit but does not prove any universal property. It was a non-trivial extension to show this.

Logical char-  
acterization

Approximation  
by finite  
spaces

Conclusion

We can now consider the LAMP structure. We do not get a universal property in the category **AMP**, however, the universality of the construction in **Rad<sub>=</sub>** almost forces the structure of a LAMP on the projective limit constructed in **Rad<sub>=</sub>**.

## LAMP on the projective limit

A LAMP can be defined on the projective limit constructed in **Rad<sub>=</sub>** so that the cone formed by this limit object and the maps to the finite approximants yields a commuting diagram in the category **AMP**.

## Two routes to the minimal realization

Given an AMP  $(X, \Sigma, p, \tau_a)$ , the projective limit of its finite approximants  $(\text{proj lim } \hat{X}, \Gamma, \gamma, \zeta_a)$  is isomorphic to its minimal realization  $(\tilde{X}, \Xi, r, \xi_a)$ .
