Probabilistic Languages and Semantics

Prakash Panangaden\textsuperscript{1}

\textsuperscript{1}School of Computer Science
McGill University

TIFR Mumbai 13th January 2015
Outline

1. Introduction
2. Conditional probability
3. Measures and measurable functions
4. Probabilistic relations
5. Probabilistic transition systems and probabilistic bisimulation
6. Semantics of a language with while loops
What am I trying to do?

1. Probability as logic: the central role of conditional probability.
2. Describe the key mathematical concepts behind modern probability: measure and integration.
3. Probabilistic systems and bisimulation (briefly)
4. Semantics of programming languages: part II.
What I am not trying to do

- Drown you in category theory.
- Discuss applications to *e.g.* Bayes nets.
- Discuss metrics or approximation theory.
- Deal with continuous time.
- Prove everything in detail (or anything at all!).
Imagine a town where every birth is equally likely to give a boy or a girl. \( \Pr(\text{boy}) = \Pr(\text{girl}) = \frac{1}{2} \).

Each birth is an independent random event.

There is a family with two children.

One of them is a boy (not specified which one), what is the probability that the other one is a boy?

Since the births are independent, the probability that the other child is a boy should be \( \frac{1}{2} \). Right?

Wrong! Before you are given the additional information that one child is a boy, there are 4 equally likely situations: bb, bg, gb, gg.

The possibility gg is ruled out. So of the three equally likely scenarios: bb, bg, gb, only one has the other child being a boy. The correct answer is \( \frac{1}{3} \).

If I had said, “The elder child is a boy”, then the probability that the other child is a boy is indeed \( \frac{1}{2} \).
Conditional probability is tricky!

Conditional probability/expectation is \textit{the} heart of probabilistic reasoning.

Conditioning = revising probability (expectation) values in the presence of new information.

Analogous to \textit{inference} in ordinary logic.
Basic Terminology

- Sample space: set of possible outcomes; $X$.
- Event: subset of the sample space; $A, B \subset X$.
- Probability: $\Pr : X \rightarrow [0, 1], \sum_{x \in X} \Pr(x) = 1$.
- Probability of an event $A$: $\Pr(A) = \sum_{x \in A} \Pr(x)$.
- $A, B$ are independent: $\Pr(A \cap B) = \Pr(A) \cdot \Pr(B)$.
- Subprobability: $\sum_{x \in X} \Pr(x) \leq 1$. 
Definition

If $A$ and $B$ are events, the conditional probability of $A$ given $B$, written $\Pr(A \mid B)$, is defined by:

$$\Pr(A \mid B) = \frac{\Pr(A \cap B)}{\Pr(B)}.$$

What happens if $\Pr(B) = 0$?
Bayes’ Rule

\[ \Pr(A \mid B) = \frac{\Pr(B \mid A) \cdot \Pr(A)}{\Pr(B)}. \]

- Trivial proof: calculate from the definition.
- Example: Two coins, one fake (two heads) one OK. One coin chosen with equal probability and then tossed to yield a H. What is the probability the coin was fake?
- Answer: \(\frac{2}{3}\).
- Bayes’ rule shows how to update the prior probability of \(A\) with the new information that the outcome was \(B\): this gives the posterior probability of \(A\) given \(B\).
A random variable \( r \) is a real-valued function on \( X \).

The expectation value of \( r \) is

\[
\mathbb{E}[r] = \sum_{x \in X} \Pr(x) r(x).
\]

The conditional expectation value of \( r \) given \( A \) is:

\[
\mathbb{E}[r \mid A] = \sum_{x \in X} r(x) \Pr(\{x\} \mid A).
\]

Conditional probability is a special case of conditional expectation.

Model and reason about systems with *continuous* state spaces.

- Hybrid control systems; e.g. flight management systems.
- Telecommunication systems with spatial variation; e.g. mobile (cell) phones.
- Performance modelling.
- Continuous time systems.
- Probabilistic programming languages with recursion.
Basic fact: There are subsets of $\mathbb{R}$ for which no sensible notion of size can be defined.

More precisely, there is no translation-invariant measure defined on all the subsets of the reals.
Countability is the key: basic analysis works well with countable summations.

A $\sigma$-algebra $\Omega$ on a set $X$ is a family of subsets with the following conditions:

1. $\emptyset, X \in \Omega$
2. $A \in \Omega \Rightarrow A^c \in \Omega$
3. $\{A_i \in \Omega\}_{i \in \mathbb{N}} \Rightarrow \bigcup_i A_i \in \Omega$

Closure under countable intersections is automatic.

$A \in \Omega$ and $A \subset B$ or $B \subset A$ does **not** imply $B \in \Omega$.

A set with a $\sigma$-algebra $(X, \Omega)$ is called a **measurable space**.
Properties of $\sigma$-algebras

- The collection of all subsets of $X$ is always a $\sigma$-algebra.
- The intersection of any collection of $\sigma$-algebras is a $\sigma$-algebra.
- Thus, given any family $\mathcal{F}$ of subsets of $X$ there is a least $\sigma$-algebra containing them: $\sigma(\mathcal{F})$; the $\sigma$-algebra generated by $\mathcal{F}$.
- For most $\sigma$-algebras of interest a “generic” member is hard to describe. We try to work with simpler generating families.
- Because measurable sets are closed under complementation, the character of the subject is very different from topology; e.g. closure under limits.
Two Examples

- **$\mathbb{R}$**: the real line. The open intervals do not form a $\sigma$-algebra. However, they generate one: the Borel algebra.

- Let $\mathcal{A}$ be an “alphabet” of symbols (say finite) and consider $\mathcal{A}^*$: words over $\mathcal{A}$. Let $\mathcal{A}^\omega$ be finite and infinite words.

- Let $u \in \mathcal{A}^*$ and let $u \uparrow \overset{\text{def}}{=} \{ v \in \mathcal{A}^\omega \mid u \leq v \}$.

- A “natural” $\sigma$-algebra on $\mathcal{A}^\omega$ is the $\sigma$-algebra generated by $\{ u \uparrow \mid u \in \mathcal{A}^* \}$.
Measurable functions

- \( f : (X, \Sigma) \longrightarrow (Y, \Omega) \) is \textit{measurable} if for every \( B \in \Omega \), \( f^{-1}(B) \in \Sigma \).
- Just like the definition of continuous in topology.
- Why is this the definition? Why backwards?
- \( x \in f^{-1}(B) \) if and only if \( f(x) \in B \).
- No such statement for the forward image.
- Exactly the same reason why we give the Hoare triple for the assignment statement in terms of preconditions.
- Older books (Halmos) give a more general definition that is not compositional.
Examples

- If \( A \subset X \) is a measurable set, \( 1_A(x) = 1 \) if \( x \in A \) and 0 otherwise is called the *indicator* or *characteristic* function of \( A \) and is measurable.

- The sum and product of real-valued measurable functions is measurable.

- If we take *finite* linear combinations of indicators we get *simple* functions: measurable functions with finite range.
Convergence properties

- If \( \{f_i : \mathbb{R} \to \mathbb{R}\}_{i \in \mathbb{N}} \) converges pointwise to \( f \) and all the \( f_i \) are measurable then so is \( f \).
- Stark difference with continuity.
- If \( f : (X, \Sigma) \to (\mathbb{R}, \mathcal{B}) \) is non-negative and measurable then there is a sequence of non-negative simple functions \( s_i \) such that \( s_i \leq s_{i+1} \leq f \) and the \( s_i \) converge pointwise to \( f \).
- The secret of integration.
Want to define a “size” for measurable sets.

A measure on \((X, \Sigma)\) is a function \(\mu : \Sigma \rightarrow [0, \infty]\) or \(\mu : \Sigma \rightarrow [0, 1]\) (probability) such that

1. \(\mu(\emptyset) = 0\)
2. \(A \cap B = \emptyset\) implies \(\mu(A \cup B) = \mu(A) + \mu(B)\).
3. \(A \subset B\) implies \(\mu(A) \leq \mu(B)\), follows.
4. \(\{A_i\}_{i \in \mathbb{N}} \subset \Sigma\) pairwise disjoint implies \(\mu(\bigcup_i A_i) = \sum_i \mu(A_i)\);
   subsumes (2).
5. \(\mu\) is continuous with respect to upward and downward chains of sets; follows from (4).
6. Actually, (4) is the only axiom needed.
Examples of measures

- $X$ countable, $\sigma$-algebra all subsets of $X$; $c(A) =$ number of elements in $A$. Counting measure; not very useful.
- $X$ any set, $\sigma$-algebra $\mathcal{P}(X)$, fix $x_0 \in X$ $\delta_{x_0}(A) = 1$ if $x_0 \in A$, 0 otherwise. Dirac delta “function.”
- $X = \mathbb{R}$, $\sigma$-algebra generated by the open (or closed) intervals, the Borel sets $\mathcal{B}$. $\lambda : \mathcal{B} \to \mathbb{R}_{\geq 0}$ defined as the measure which assigns to intervals their lengths.
- How do we know that such a measure is defined or that it is unique?
- Similarly, we can define measures on $\mathbb{R}^n$. 

We look for simple “well-structured” families of sets, e.g. intervals in $\mathbb{R}$ and define “suitable” functions on them.

Then we rely on extension theorems to obtain a unique measure on the generated $\sigma$-algebra.

I will skip the “well-structured” conditions on the family of sets and the definition of “suitable” functions.

A $\pi$-system is a family of sets closed under finite intersection.

If two measures agree on a $\pi$-system then they agree on the generated $\sigma$-algebra.

Fantastically useful!!
The Lebesgue integral

- Want to define $\int f \, d\mu$, where $f$ is measurable and $\mu$ is a measure.
- Assume that $f$ is everywhere non-negative and bounded and $\mu$ is a probability measure.
- If $f$ is $1_A$ then we define $\int 1_A \, d\mu = \mu(A)$.
- If $f$ is $r \cdot 1_A$ then we define $\int f \, d\mu = r \cdot \mu(A)$.
- If $f = \sum_{i=1}^{k} r_i 1_{A_i}$ (simple function) then we define

$$\int f \, d\mu = \sum_{i=1}^{k} r_i \cdot \mu(A_i).$$

- Need to check that it does not matter how we write such an $f$ as a simple function.
- There are some subtleties if sets can have infinite measure but these do not arise if we are dealing with probability measures and bounded measurable functions.
The Lebesgue integral II

The Lebesgue integral

If $f$ is non-negative and measurable and $\mu$ a probability measure we define

$$\int f\,d\mu = \sup \int s\,d\mu$$

where the $\sup$ is over all simple non-negative functions below $f$.

- One can define integrals of general functions by splitting them into positive and negative pieces.
- One can prove that the integral is linear and monotone.
The monotone convergence theorem

Let \( \{f_n\} \) be a sequence of measurable functions on \( X \) such that (1)
\[
\forall x \in X, \ 0 \leq f_1(x) \leq f_2(x) \leq \ldots \leq f_n(x) \leq \ldots \leq f(x)
\]
and (2)
\[
\forall x \in X, \ \sup_n f_n(x) = f(x)
\]
then

\[
\sup_n \int f_n \, d\mu = \int f \, d\mu.
\]

- Should remind you of things in domain theory.
- The integral is continuous in an order-theoretic sense.
The monotone convergence mantra

- Want to prove $\int \mathcal{E}(f) \, d\mu = \int \mathcal{E}'(f) \, d\nu$.
- Prove it for the special case $f = 1_A$, usually easy.
- Then automatic for simple functions by linearity.
- Then automatic for non-negative bounded measurable functions by the monotone convergence theorem.
- Then clear for general bounded measurable functions.
Ordinary binary relations

- $R : A \rightarrow B$ is just $R \subseteq A \times B$
- Natural converse relation $R^\circ : B \rightarrow A$.
- Composition: $R_1 : A \rightarrow B$, $R_2 : B \rightarrow C$ then $R_1 \circ R_2 = \{ (x, z) \exists y \in B, xR_1 y \text{ and } yR_2 z \}$.
- Close relation with the powerset construction:
  - $\hat{R} : A \rightarrow \mathcal{P}(B)$ is an equivalent description of $R$. 

Panangaden (McGill University)  Probabilistic Languages  POPL 2015 Tutorial  27 / 43
Markov kernels

- A *Markov kernel* on a measurable space \((S, \Sigma)\) is a function \(h : S \times \Sigma \to [0, 1]\) with (a) \(h(s, \cdot) : \Sigma \to [0, 1]\) a (sub)probability measure and (b) \(h(\cdot, A) : X \to [0, 1]\) a measurable function.

- Though apparently asymmetric, these are the probabilistic analogues of binary relations and the uncountable generalization of a matrix.

- They describe transition probabilities in situations where a “point-to-point” approach does not make sense.

- Composition: \(k \text{ “after” } h, (k \circ h)(x, A) = \int k(x', A)dh(x, \cdot), \) where we are integrating the variable \(x'\) using the measure \(h(x, \cdot)\).

- We construct these things using a major theorem (the Radon-Nikodym theorem).
Want to define $R : (X, \Sigma) \rightarrow (Y, \Omega)$. 

Define a probabilistic relation $R$ from $X$ to $Y$ to be a Markov kernel of type $R : X \times \Omega \rightarrow [0, 1]$ with the same measurability conditions.

Given relations $R_1 : (X, \Sigma) \rightarrow (Y, \Omega)$ and $R_2 : (Y, \Omega) \rightarrow (Z, \Lambda)$ we define $R_2 \circ R_1 \ (R_1; R_2)$ as

$$(R_2 \circ R_1)(x, C \in \Lambda) = \int R_2(y, C)R_1(x, \cdot)\,d.$$

Just like the formula for composing ordinary relations with integration for $\exists$.

Converse is tricky and requires more machinery and more structure.
The category SRel

- **Objects**: measurable spaces \((X, \Sigma_X)\)
- **Morphisms**: \(h : (X, \Sigma_X) \rightarrow (Y, \Sigma_Y)\) are Markov kernels \(h : X \times \Sigma_Y \rightarrow [0, 1]\).
- **Composition**: \(h : X \rightarrow Y, k : Y \rightarrow Z\) then \(\forall x \in X, C \in \Sigma_Z, (k \circ h)(x, C) = \int_Y k(y, C)h(x, dy)\).
- **The identity morphisms**: \(id : X \rightarrow X\) is \(\delta(x, A)\).
- **Prove associativity of composition by using the monotone convergence mantra.**
- **It has countable coproducts; very useful for semantics.**
- **Unlike Rel this category is not self dual.**
Define $\Pi : \mathbf{Mes} \to \mathbf{Mes}$ by $\Pi((X, \Sigma_X)) = \{\nu | \nu : \Sigma_X \to [0, 1]\}$ where $\nu$ is a subprobability measure on $X$.

Actually, Gíry used probability measures; I made the small change to subprobability measures in order to adapt it to programming language semantics.

But $\Pi(X)$ has to be a measurable space not just a set.

For every $A \in \Sigma_X$ we define $\text{ev}_A : \Pi(X) \to [0, 1]$ by $\text{ev}_A(\nu) = \nu(A)$.

We define the $\sigma$-algebra on $\Pi(X)$ to be the least $\sigma$-algebra making all the $\text{ev}_A$ measurable.

Given $f : X \to Y$ define $(\Pi(f)(\nu))(B \in \Sigma_Y) = \nu(f^{-1}(B))$.

Need natural transformations: $\eta : I \to \Pi$ and $\mu : \Pi^2 \to \Pi$.

$\eta_X(x) = \delta(x, \cdot)$

$\mu_X(\Omega \in \Pi^2(X)) = \lambda B \in \Sigma_X. \int \text{ev}_B \, d\Omega_{\Pi(X)}$. 
The Kleisli category of $\Pi$

- If $T : C \rightarrow C$ is a monad, then $C_T$ has the same objects as $C$ and the morphisms in $C_T$ from $X$ to $Y$ are morphisms in $C$ from $X$ to $TY$.

- For the powerset monad we get morphisms $X \rightarrow \mathcal{P}(Y)$ which we recognize as just binary relations.

- Here we get $h : X \rightarrow \Pi(Y)$ or $h : X \rightarrow (\Sigma_Y \rightarrow [0, 1])$ or $h : X \times \Sigma_Y \rightarrow [0, 1]$.

- These are exactly the Markov kernels.
Labelled Markov processes are probabilistic versions of labelled transition systems. Labelled transition systems where the final state is governed by a probability distribution - no other indeterminacy.

All probabilistic data is *internal* - no probabilities associated with environment behaviour.

We observe the interactions - not the internal states.

**In general, the state space of a labelled Markov process may be a *continuum***.
An LMP is a tuple \((S, \Sigma, L, \forall \alpha \in L. \tau_\alpha)\) where \(\tau_\alpha : S \times \Sigma \to [0, 1]\) is a transition probability function such that

\[\forall s : S. \lambda A : \Sigma. \tau_\alpha(s, A)\]

is a subprobability measure and

\[\forall A : \Sigma. \lambda s : S. \tau_\alpha(s, A)\]

is a measurable function.
Let $S = (S, \Sigma, \tau)$ be a labelled Markov process. An equivalence relation $R$ on $S$ is a **bisimulation** if whenever $sRs'$, with $s, s' \in S$, we have that for all $a \in A$ and every $R$-closed measurable set $A \in \Sigma$, $	au_a(s, A) = \tau_a(s', A)$.

Two states are bisimilar if they are related by a bisimulation relation.

Can be extended to bisimulation between two different LMPs.
Logical Characterization

\( \mathcal{L} ::= T \phi_1 \land \phi_2 \langle a \rangle_q \phi \)

We say \( s \models \langle a \rangle_q \phi \) iff

\[ \exists A \in \Sigma. (\forall s' \in A. s' \models \phi) \land (\tau_a(s, A) > q). \]

Two systems are bisimilar iff they obey the same formulas of \( \mathcal{L} \). [DEP 1998 LICS, I and C 2002]
Kozen’s Language

\[ S ::= x_i := f(\vec{x}) | S_1 ; S_2 | if \ B \ then \ S_1 \ else \ S_2 | while \ B \ do \ S. \]

- There are a fixed set of variables \( \vec{x} \) taking values in a measurable space \((X, \Sigma_X)\).
- \( f \) is a measurable function.
- \( B \) is a measurable subset.
Outline of the semantics

- State transformer semantics: distribution (measure) transformer semantics.
- Meaning of statements: Markov kernels \( i.e. \mathcal{SRel} \) morphisms.
- The only subtle part: how to give fixed-point semantics to the while loop?
Partially additive structure

- Back to \textbf{SRel} structure.
- Can we “add” \textbf{SRel} morphisms?
- Not always, the sum may exceed 1, but we can define \textit{summable families} which may even be countably infinite.
- The homsets of \textbf{SRel} form \textit{partially additive monoids}.
- The sums can be rearranged at will (partition-associativity).
- Limit property: If $F$ is a countable family in which every \textit{finite} subfamily is summable then $F$ is summable.
- In the category \textbf{SRel}, the sums interact properly with composition.
- If $\{f_i \mid i \in \mathbb{N}\}$ is a countable set of morphisms from $X$ to $Y$ and there is a morphism $f : X \to (Y + Y + \ldots)$ such that when projected onto the $X$’s we get the $f_i$, then the family is summable.
Given a partially additive category $\mathcal{C}$ and $f : X \rightarrow X + Y$ we can find a unique pair $f_1 : X \rightarrow X$ and $f_2 : X \rightarrow Y$ such that $f = \iota_1 \circ f_1 + \iota_2 \circ f_2$. Furthermore, there is a morphism $f^* : X \rightarrow Y$ given by

\[
 f^* = \sum_{n=0}^{\infty} f_2 \circ f_1^n.
\]

The theorem says that the family $f_2 \circ f_1^n$ is summable. It is the \textit{iterate} of $f$. 

Statements are SRel morphisms of type \((X^n, \Sigma^n) \rightarrow (X^n, \Sigma^n)\).

**Assignment:** \(x := f(\vec{x})\)

\[\llbracket x := f(\vec{x}) \rrbracket(\vec{x}, \vec{A}) = \delta(x_1, A_1) \ldots \delta(x_{i-1}, A_{i-1})\delta(f(\vec{x}), A_i)\delta(x_{i+1}, A_{i+1}) \ldots\]

**Sequential Composition:** \(S_1; S_2\)

\[\llbracket S_1; S_2 \rrbracket = \llbracket S_2 \rrbracket \circ \llbracket S_1 \rrbracket\]

where the composition on the right hand side is the composition in SRel.

**Conditionals:** if \(B\) then \(S_1\) else \(S_2\)

\[\llbracket\text{if } B \text{ then } S_1 \text{ else } S_2 \rrbracket(\vec{x}, \vec{A}) = \delta(\vec{x}, B)\llbracket S_1 \rrbracket(\vec{x}, \vec{A}) + \delta(\vec{x}, B^c)\llbracket S_2 \rrbracket(\vec{x}, \vec{A})\]
**While Loops:** *while B do S*

\[
\semantics{ \text{while } B \text{ do } S } = h^* 
\]

where we are using the \( \ast \) in \textit{SRel} and the morphism

\[
h : (X^n, \Sigma^n) \rightarrow (X^n, \Sigma^n) + (X^n, \Sigma^n)
\]

is given by

\[
h(\vec{x}, A_1 \uplus A_2) = \delta(\vec{x}, B) \semantics{S}(\vec{x}, A_1) + \delta(\vec{x}, B^c)\delta(\vec{x}, A_2).
\]
We can construct a category of probabilistic predicate transformers: \( \text{SPT} \).

Objects are measurable spaces.

Given \((X, \Sigma_X)\) we can construct the (Banach) space of bounded measurable functions on \(X\) (the “predicates”) \(\mathcal{F}(X)\).

A morphism \(X \to Y\) in \(\text{SPT}\) is a bounded (continuous) linear map from \(\mathcal{F}(X)\) to \(\mathcal{F}(Y)\).

\[
\text{SPT} \simeq \text{SRel}^{op}.
\]

This gives us the structure needed for a \text{wp} semantics.
